BERNOULLI PROBLEM FOR ROUGH DOMAINS

FRANÇOIS BOUCHON AND LAURENT CHUPIN

ABSTRACT. We consider the exterior free boundary Bernoulli problem in the case of a rough given domain. An asymptotic analysis shows that the solution of the initial problem can be approximated by the solution of a non-rough Bernoulli problem at order 2. Numerical tests confirm these theoretical results.

1. INTRODUCTION

The free Boundary Bernoulli problem is a model problem with many applications in engineering sciences such as fluid mechanics (see [13]) or electromagnetics (see [10], [11] and references therein). It consists in an overdetermined elliptic problem on a free domain whose solution is the domain itself as well as the potential (see [12] for a review). More precisely, let Ω be a bounded open set, we look for a domain A containing $\overline{\Omega}$ and a function u defined on $A \setminus \overline{\Omega}$ such that:

$$(1) \quad \begin{cases} \Delta u &= 0 & \text{in } A \setminus \overline{\Omega}, \\ u &= 1 & \text{on } \partial\Omega, \\ u &= 0 & \text{on } \partial A, \\ |\nabla u| &= \lambda & \text{on } \partial A. \end{cases}$$

This problem is known as "exterior Bernoulli problem", since the boundary of the solution domain ∂A is exterior to the given domain Ω. The interior Bernoulli problem is similar, with $A \subset \Omega$ and then u defined (and harmonic) on $\Omega \setminus \overline{A}$.

Theoretical questions have been addressed concerning existence or uniqueness of solution as well as geometric properties. In [7], Beurling proposed a classification of solutions (elliptic, parabolic and hyperbolic) and introduced the method of sub- and super-solution to prove the existence and uniqueness of the elliptic solution in two-dimensions. This method was later adapted by Acker in [2] to get the same result in higher dimension in the case of a convex given domain Ω. The same result was also proved by Alt and Caffarelli in [4] using variational methods. Henrot and Shahgholian showed in [17] that, if Ω is convex, then the solution domain A is convex. They also give a positive answer to this question for the p-Laplacian case in [18] and [19].

Acker and Meyer considered the more general starlike case in [3], and showed that the solution domain is starlike and elliptic. Using both geometric arguments and variational methods, they also proved that the solution domain depends continuously on the data (see also [16]).

Another class of works consider the numerical solution of this free boundary problem, most of them consisting in iterative algorithms which build a sequence of domains converging to the solution domain. A fixed point type approach have been introduced by Flucher and Rumpf in [12], and later combined with a levelset approach in [8]. Some numerical methods based on shape functional minimization have also been developped in [6], [15] and [20], and for the three dimensional case in [14].

In most situations of physical relevance, the given domain Ω is issued from industrial situations and its boundary is generally rough. Such geometry can not be described in detail: either the precise shape of the roughness is unknown, or its spatial variations are too small for computational grids. Therefore, one may only hope to account for the averaged effect of the irregularities.

Such an approach is usually used for Stokes flows: the irregular boundary is replaced by an artificial smoothed one, and an artificial boundary condition (a wall law) is prescribed there, that should reflect the mean impact of the roughness, see for instance [1, 5, 9, 21, 22].
Roughly speaking, to obtain a "wall law" the method consists in correcting the flow without roughnesses using a contribution located in the neighborhood of the actual boundary. The mathematical proofs are then based on the justification of the "local" correction.

The goal of the present article is to obtain a kind of "wall law" for a Bernoulli problem when the given domain Ω is assumed to be rough. For the Bernoulli problem the main difficulty is that the unknown is not only a function but also the domain in which this function is defined. We then propose to study a simple case: we consider that the rough domain is a perturbation of a ball in $\mathbb{R}^2$, and that the perturbation is given as a periodic function of amplitude and period equal to ε. We discuss in the conclusion, see section 5 some possible extensions of these results.

The rest of this paper is composed of three main parts. Section 2 is devoted to the presentation of the problem and its mathematical framework. We also give the main result. The proof of this result is detailed in Section 3 whereas some numerical simulations are given in Section 4. Finally, some technical results are postponed in Appendix.

2. STATEMENT OF THE PROBLEM AND MAIN RESULTS

The Bernoulli problem that we consider reads: given a constant $\lambda > 0$ and a domain $\Omega_\varepsilon \subset \mathbb{R}^2$, find a domain A_ε containing Ω_ε and function u_ε defined on $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$ such that:

$$(2) \qquad \begin{cases} \Delta u_\varepsilon & = & 0 & \text{in } A_\varepsilon \setminus \overline{\Omega_\varepsilon}, \\ u_\varepsilon & = & 1 & \text{on } \partial\Omega_\varepsilon, \\ u_\varepsilon & = & 0 & \text{on } \partial A_\varepsilon, \\ |\nabla u_\varepsilon| & = & \lambda & \text{on } \partial A_\varepsilon. \end{cases}$$

The parameter $\varepsilon > 0$ models the size of the roughness of the domain Ω_ε. More precisely we consider a domain Ω_ε defined using polar coordinates:

$$(3) \qquad \Omega_\varepsilon = \left\{ (r,\theta) \in \mathbb{R}_+ \times \mathbb{T}^1 \; ; \; r < 1 - \varepsilon h\left(\frac{\theta}{\varepsilon}\right) \right\},$$

where $\mathbb{T}^1 = \mathbb{R}/(2\pi\mathbb{Z})$ denotes the torus, and where h is a Lipschitz function on $\mathbb{T}^1$.
Note that a function f defined on $\mathbb{T}^1$ can be viewed as a 2π-periodic function $\widetilde{f}$ defined on $\mathbb{R}$. Hence the parameter ε must be the inverse of an integer number: $\frac{1}{\varepsilon} \in \mathbb{N}$, and it must be small enough: $\frac{1}{\varepsilon} > \max_{\mathbb{T}^1} h$. We define the measure $\mathrm{d}\Theta$ as the measure quotient, that is such that

$$\int_{\mathbb{T}^1} f(\Theta)\, \mathrm{d}\Theta = \int_0^{2\pi} \widetilde{f}(t) \frac{\mathrm{d}t}{2\pi}.$$

We note Ω_0 the domain without roughness, that is $\Omega_0 = \mathcal{B}(0,1)$. The function h is assumed to be a lipschitz and nonnegative function. That implies $\Omega_\varepsilon \subset \Omega_0$ for all $\varepsilon > 0$. Note that using these polar coordinates (r,θ) the Laplacian operator reads

$$\Delta = \frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}.$$

For such a context, it is known that the Bernoulli problem (2) has a unique solution, see [3]. In fact this existence results from the fact that the domain Ω_ε is starlike with respect to all points in a ball $\mathcal{B}(0,\delta)$.

In order to approach this problem (2) for $\varepsilon \to 0$ using a Bernoulli problem on the non-rough domain Ω_0, the most natural idea is to introduce the following Bernoulli problem: find a

domain A_0 containing Ω_0 and function u_0 defined on $A_0 \setminus \overline{\Omega_0}$ such that

(4)
$$\begin{cases} \Delta u_0 & = & 0 & \text{in } A_0 \setminus \overline{\Omega_0}, \\ u_0 & = & 1 & \text{on } \partial\Omega_0, \\ u_0 & = & 0 & \text{on } \partial A_0, \\ |\nabla u_0| & = & \lambda & \text{on } \partial A_0. \end{cases}$$

This approach is mathematically justified by the continuity results of [3] (see also [16]). More precisely we have

Proposition 1. *The solution (A_0, u_0) of the Bernoulli problem* (4) *approaches the solution $(A_\varepsilon, u_\varepsilon)$ of the Bernoulli problem* (2) *at order one:*

(5)
$$\mathcal{D}_\mathcal{H}(A_0, A_\varepsilon) = \mathcal{O}(\varepsilon).$$

The proof of this proposition directly follows from Theorem 3.9 in [3]. More precisely it expresses that $d_2(\partial A_0, \partial A_\varepsilon) \leq d_2(\partial\Omega_0, \partial\Omega_\varepsilon)$ where d_2 is the metric defined by: $d_2(\Gamma_1, \Gamma_2) = \sup\{|\ln(\gamma)|, \gamma \in \mathbb{R}_+ \; ; \; \gamma\Gamma_1 \cap \Gamma_2 \neq \emptyset\}$. For $0 < \delta < M$, we introduce the set

$\mathcal{K} = \{\partial\Omega \text{ where } \Omega \subset \mathcal{B}(0, M) \text{ is a starlike domain with respect to all points in } \mathcal{B}(0, \delta)\}.$

We observe that there exists a choice of δ, M and ε_0 such that $\partial\Omega_\varepsilon \in \mathcal{K}$ and $\partial A_\varepsilon \in \mathcal{K}$ for all $0 \leq \varepsilon < \varepsilon_0$ (see [3]). Then, using the equivalence between this metric and the Hausdorff distance on the set $\mathcal{K}$, see Appendix A, the following relation on the data $\mathcal{D}_\mathcal{H}(\partial\Omega_0, \partial\Omega_\varepsilon) = \mathcal{O}(\varepsilon)$ now implies (5).

To obtain better estimate, we introduce the following problem: Given a constant B_0, find a domain A_ε^0 containing Ω_0 and function u_ε^0 defined on $A_\varepsilon^0 \setminus \overline{\Omega_0}$ such that

(6)
$$\begin{cases} \Delta u_\varepsilon^0 & = & 0 & \text{in } A_\varepsilon^0 \setminus \overline{\Omega_0}, \\ u_\varepsilon^0 & = & 1 & \text{on } \partial\Omega_0, \\ u_\varepsilon^0 & = & -\varepsilon B_0 & \text{on } \partial A_\varepsilon^0, \\ |\nabla u_\varepsilon^0| & = & \lambda & \text{on } \partial A_\varepsilon^0. \end{cases}$$

The main result presented in this paper is the following:

Theorem 1. *There exists $B_0 \in \mathbb{R}$ such that the solution $(A_\varepsilon^0, u_\varepsilon^0)$ of the Bernoulli problem* (6) *approaches the solution $(A_\varepsilon, u_\varepsilon)$ of the Bernoulli problem* (2) *at order two:*

(7)
$$\mathcal{D}_\mathcal{H}(A_\varepsilon^0, A_\varepsilon) = \mathcal{O}(\varepsilon^2).$$

For explicit calculations, the constant B_0 can be determined as follows. We introduce the cell domain

(8)
$$\omega = \{(R, \Theta) \in \mathbb{R} \times \mathbb{T}^1 \; ; \; R > -h(\Theta)\}.$$

We solve the Laplace problem: Find a function $\widetilde{u}_1$ defined on ω, periodic with respect to Θ, with $\widetilde{\nabla}\widetilde{u}_1 \in L^2(\omega)$ and such that

(9)
$$\begin{cases} \widetilde{\Delta}\widetilde{u}_1 & = & 0 & \text{in } \omega, \\ \widetilde{u}_1(-h(\Theta), \Theta) & = & -h(\Theta) & \text{on } \partial\omega. \end{cases}$$

For such a function defined on the domain ω the Laplacian operator reads:

$$\widetilde{\Delta} = \frac{\partial^2}{\partial R^2} + \frac{\partial^2}{\partial\Theta^2}.$$

The constant B_0 is then given by

(10)
$$B_0 = \lambda\rho_0 \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, \mathrm{d}\Theta,$$

the constant ρ_0 corresponds to the radius of the domain A_0 solution of the simple Bernoulli problem (4).

Remark 1. *One of the key point of the proof is an estimate of kind:*

$$\|u_\varepsilon - (u_\varepsilon^0 + \varepsilon\,\widetilde{u}_\varepsilon^1)\|_{L^\infty(A_\varepsilon\setminus\overline{\Omega_\varepsilon})} = \mathcal{O}(\varepsilon^2), \tag{11}$$

for an "oscillating" function $\widetilde{u}_\varepsilon^1$ which exponentially decreases to the constant B_0 far from the boundary $\partial\Omega_\varepsilon$.

3. Proofs

3.1. **Well posedness.** First we prove that all the problems introduced in section 2 have a unique solution.

3.1.1. *Bernoulli problems.* The problems (4) and (6) are Bernoulli problems where the given domain is the unit ball $\Omega_0 = \mathcal{B}(0,1)$. Consequently, their solution can be explicitly given (see for instance [12]):
• The solution (A_0, u_0) of the problem (4) is invariant under rotation. It writes $A_0 = \mathcal{B}(0, \rho_0)$ where $\rho_0 > 1$ satisfies:

$$\lambda\,\rho_0 \ln\rho_0 = 1, \tag{12}$$

and the function u_0 is defined using polar coordinates by:

$$u_0(r, \theta) = \frac{\ln(\rho_0) - \ln(r)}{\ln(\rho_0)}. \tag{13}$$

• In the same way, we have $A_\varepsilon^0 = \mathcal{B}(0, \rho_\varepsilon^0)$ where the constant ρ_ε^0 satisfies

$$\lambda\,\rho_\varepsilon^0 \ln\rho_\varepsilon^0 = 1 + B_0\varepsilon. \tag{14}$$

The explicit expression for u_ε^0 is then given by:

$$u_\varepsilon^0(r, \theta) = (1 + B_0\varepsilon)\frac{\ln(\rho_\varepsilon^0) - \ln(r)}{\ln(\rho_\varepsilon^0)} - B_0\varepsilon. \tag{15}$$

• The domain Ω_ε is defined using a graph of a lipschitz function (more precisely the function $\theta \mapsto 1 - \varepsilon h(\theta/\varepsilon)$). Consequently this domain is starlike with respect to all points in an open ball centered at the origin. We have the following existence result, proved in [3]:

Proposition 2. *The Bernoulli problem* (2) *has a unique solution. Moreover, the given domain Ω_ε being starlike with respect to all points in an open ball, the domain solution A_ε is also starlike with respect to all points the same open ball.*

As a consequence of this result, the boundary of the domain A_ε can be writen as the graph of a lipschitz function:

$$\partial A_\varepsilon = \{(r, \theta) \in \mathbb{R}_+ \times \mathbb{T}^1 \; ; \; r = \rho_\varepsilon(\theta)\}. \tag{16}$$

3.1.2. *Cell problem.* For the cell problem (9), an existence result of $\widetilde{u}_1$ is given for instance in [22]. Moreover we have the following result:

Proposition 3. *For all $(R, \Theta) \in \mathbb{R}_+ \times \mathbb{T}^1$ we have*

$$\widetilde{u}_1(R, \Theta) = \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta)\,\mathrm{d}\Theta + \sum_{k\in\mathbb{Z}\setminus\{0\}} \alpha_k\,\mathrm{e}^{-|k|R}\,\mathrm{e}^{ik\Theta}, \tag{17}$$

where each α_k is a constant.

Proof - We use the Fourier decomposition of the solution $\widetilde{u}_1$ with respect to the periodic variable Θ. The Laplace equation results in an ordinary differential equation on each Fourier coefficient. The proposition is then a consequence of the condition $\widetilde{\nabla}\widetilde{u}_1 \in L^2(\omega)$.

Corollary 1. *For all $\mu < 1$ there exists $C(\mu) \geq 0$ such that for all $(R, \Theta) \in \mathbb{R}_+ \times \mathbb{T}^1$ we have:*

$$(18) \qquad \begin{aligned} \left| \widetilde{u}_1(R, \Theta) - \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, \mathrm{d}\Theta \right| &\leq C(\mu) \, \mathrm{e}^{-\mu R}, \\ \left| \widetilde{\nabla} \widetilde{u}_1(R, \Theta) \right| &\leq C(\mu) \, \mathrm{e}^{-\mu R}. \end{aligned}$$

3.2. **Laplace system with oblique boundary conditions for the error.** Now we prove the estimate announced in Remark 1.

3.2.1. *Building of the function $\widetilde{u}_\varepsilon^1$.*

• Besides the introduction of the function $\widetilde{u}_1$, we introduce by induction the following functions as solution of Laplace problems on the cell domain ω: The functions $\widetilde{u}_j$, $j \geq 2$, periodic with respect to Θ, with $\widetilde{\nabla} \widetilde{u}_j \in L^2(\omega)$ and such that:

$$(19) \qquad \begin{cases} \widetilde{\Delta} \widetilde{u}_j = \displaystyle\sum_{k=1}^{j-1} (-1)^{j-k} R^{j-k-1} \left(\dfrac{\partial \widetilde{u}_k}{\partial R} - (j-k+1) R \dfrac{\partial^2 \widetilde{u}_k}{\partial \Theta^2} \right) & \text{in } \omega, \\ \widetilde{u}_j(-h(\Theta), \Theta) = 0 & \text{on } \partial\omega. \end{cases}$$

Note that the behavior of these functions $\widetilde{u}_j$, $j \geq 2$, for large values of R is similar to those of the function $\widetilde{u}_1$ (see Proposition 3 and Corollary 1). By induction on j we prove that the right hand side members of the Laplace equation (19) are free average with respect to the periodic variable Θ and, like in the proof of the proposition 3, see also the same kind of proof in [9], the following results:

Proposition 4. *For each $j \geq 2$ there exists a solution $\widetilde{u}_j$ of the Laplace problem (19). Moreover for $(R, \Theta) \in \mathbb{R}_+ \times \mathbb{T}^1$ we have*

$$(20) \qquad \widetilde{u}_j(R, \Theta) = \int_{\mathbb{T}^1} \widetilde{u}_j(0, \Theta) \, \mathrm{d}\Theta + \sum_{k \in \mathbb{Z} \setminus \{0\}} \alpha_{k,j}(R) \, \mathrm{e}^{-|k|R} \, \mathrm{e}^{ik\Theta},$$

where each $\alpha_{k,j}$ is a polynomial function. In particular for all $\mu < 1$ there exists $C(\mu) \geq 0$ such that for $(R, \Theta) \in \mathbb{R}_+ \times \mathbb{T}^1$ we have

$$(21) \qquad \begin{aligned} \left| \widetilde{u}_j(R, \Theta) - \int_{\mathbb{T}^1} \widetilde{u}_j(0, \Theta) \, \mathrm{d}\Theta \right| &\leq C(\mu) \, \mathrm{e}^{-\mu R}, \\ \left| \widetilde{\nabla} \widetilde{u}_j(R, \Theta) \right| &\leq C(\mu) \, \mathrm{e}^{-\mu R}. \end{aligned}$$

• We introduce

$$(22) \qquad \widetilde{u}_\varepsilon^1(r, \theta) = \lambda \rho_0 \sum_{j=1}^{J} \varepsilon^{j-1} \widetilde{u}_j \left(\dfrac{r-1}{\varepsilon}, \dfrac{\theta}{\varepsilon} \right),$$

the value of the integer J will be later selected. Due to the change of variable $R = \dfrac{r-1}{\varepsilon}$, $\Theta = \dfrac{\theta}{\varepsilon}$ we have for each $j \geq 1$:

$$\Delta \left[\widetilde{u}_j \left(\dfrac{r-1}{\varepsilon}, \dfrac{\theta}{\varepsilon} \right) \right] = \dfrac{1}{\varepsilon^2} \dfrac{\partial^2 \widetilde{u}_j}{\partial R^2}(R, \Theta) + \dfrac{1}{\varepsilon(1 + \varepsilon R)} \dfrac{\partial \widetilde{u}_j}{\partial R}(R, \Theta)$$
$$+ \dfrac{1}{\varepsilon^2 (1 + \varepsilon R)^2} \dfrac{\partial^2 \widetilde{u}_j}{\partial \Theta^2}(R, \Theta).$$

We deduce the following asymptotic development with respect to ε:

$$\Delta \left[\widetilde{u}_j \left(\dfrac{r-1}{\varepsilon}, \dfrac{\theta}{\varepsilon} \right) \right] = \dfrac{1}{\varepsilon^2} \widetilde{\Delta} \widetilde{u}_j(R, \Theta)$$
$$+ \sum_{k=0}^{\infty} \varepsilon^{k-1} (-1)^k R^k \left(\dfrac{\partial \widetilde{u}_j}{\partial R}(R, \Theta) - (k+2) R \dfrac{\partial^2 \widetilde{u}_j}{\partial \Theta^2}(R, \Theta) \right).$$

• By construction of $\widetilde{u}_\varepsilon^1$, see its expression (22), we deduce that $\Delta \widetilde{u}_\varepsilon^1 = \varepsilon^{J-2} F_\varepsilon$, where $F_\varepsilon(r, \theta) = \mathcal{O}(1)$ with respect to ε. Note that in the sequel we will choose $J = 3$ so that

$$\Delta \widetilde{u}_\varepsilon^1 = \mathcal{O}(\varepsilon). \tag{23}$$

• Note also that the value of the function $\widetilde{u}_\varepsilon^1$ on the boundary $\partial\Omega_\varepsilon$ is given by

$$\widetilde{u}_\varepsilon^1|_{\partial\Omega_\varepsilon} = -\lambda\,\rho_0 h\left(\frac{\cdot}{\varepsilon}\right). \tag{24}$$

• On the boundary ∂A_ε parametrised by the function ρ_ε we have, for all $\theta \in \mathbb{T}^1$

$$\widetilde{u}_\varepsilon^1(\rho_\varepsilon(\theta), \theta) - \lambda\,\rho_0 \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta)\,\mathrm{d}\Theta$$
$$= \lambda\,\rho_0 \left(\widetilde{u}_1\left(\frac{\rho_\varepsilon(\theta) - 1}{\varepsilon}, \frac{\theta}{\varepsilon}\right) - \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta)\,\mathrm{d}\Theta \right)$$
$$+ \varepsilon\lambda\,\rho_0 \sum_{j=2}^{J} \varepsilon^{j-2} \widetilde{u}_j\left(\frac{\rho_\varepsilon(\theta) - 1}{\varepsilon}, \frac{\theta}{\varepsilon}\right).$$

Using Corollary 1, Proposition 4 and the fact that for all $\theta \in \mathbb{T}^1$ we have $\rho_\varepsilon(\theta) - 1 = \mathcal{O}(1)$ (since $\lim_{\varepsilon\to0} \rho_\varepsilon(\theta) = \rho_0$ for all $\theta \in \mathbb{T}^1$, see [3]) we deduce

$$\left| \widetilde{u}_\varepsilon^1|_{\partial A_\varepsilon} - \lambda\,\rho_0 \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta)\,\mathrm{d}\Theta \right| = \mathcal{O}(\varepsilon). \tag{25}$$

• In the same way, using the estimate for the gradients in Corollary 1 and Proposition 4, we have for instance

$$\nabla \widetilde{u}_\varepsilon^1|_{\partial A_\varepsilon} = o(\varepsilon^k) \qquad \text{for all } k \in \mathbb{N}. \tag{26}$$

3.2.2. *System satisfied by the error.* We introduce the difference $v = u_\varepsilon - (u_\varepsilon^0 + \varepsilon\widetilde{u}_\varepsilon^1)$. We will prove that v satisfies a Laplace problem on the domain $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$ with oblique boundary conditions on the exterior boundary ∂A_ε.

• We are first interested in the value of Δv on $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$.
By definition of u_ε (which satisfies the Bernoulli problem (2)), we have $\Delta u_\varepsilon = 0$ on $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$. The function u_ε^0, solution of the Bernoulli problem (6), is *a priori* only defined on $A_0^0 \setminus \overline{\Omega_0}$. But its explicit expression given by (15) can be extended on $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$, by preserving the relation $\Delta u_\varepsilon^0 = 0$. Finally, the approximation (23) on the oscillating contribution $\Delta \widetilde{u}_\varepsilon^1$ implies that

$$\Delta v = \mathcal{O}(\varepsilon^2). \tag{27}$$

• The second step consists in obtaining the value of v on $\partial\Omega_\varepsilon$.
From the Bernoulli problem (2), we know that $u_\varepsilon|_{\partial\Omega_\varepsilon} = 1$.
The Taylor development of the function u_ε^0 (or more precisely its extension) implies that for all $\theta \in \mathbb{T}^1$ we have

$$u_\varepsilon^0\left(1 - \varepsilon h\left(\frac{\theta}{\varepsilon}\right), \theta\right) = u_\varepsilon^0(1, \theta) - \varepsilon h\left(\frac{\theta}{\varepsilon}\right) \partial_r u_\varepsilon^0(1, \theta) + \mathcal{O}(\varepsilon^2).$$

From the analytic expression of u_ε^0, see (15), we deduce that for all $\theta \in \mathbb{T}^1$ we have

$$u_\varepsilon^0\left(1 - \varepsilon h\left(\frac{\theta}{\varepsilon}\right), \theta\right) = 1 + \varepsilon\lambda\rho_0 h\left(\frac{\theta}{\varepsilon}\right) + \mathcal{O}(\varepsilon^2).$$

Note that we have used the relation $\rho_\varepsilon^0 = \rho_0 + \mathcal{O}(\varepsilon)$ which directly follows from the expressions of ρ_ε^0 and ρ_0 given by (15) and (13) respectively. Using the estimate (24) of $\widetilde{u}_\varepsilon^1$ on the boundary $\partial\Omega_\varepsilon$ we deduce that

$$v|_{\partial\Omega_\varepsilon} = \mathcal{O}(\varepsilon^2). \tag{28}$$

• We now compute the value of v on the boundary ∂A_ε.

By definition of the solution u_ε of the problem (2), we have $u_\varepsilon|_{\partial A_\varepsilon} = 0$.

Recall that the boundary ∂A_ε is parametrised using the function ρ_ε whereas the boundary ∂A_ε^0 is the ball $\mathcal{B}(0, \rho_\varepsilon^0)$. We deduce that for all $\theta \in \mathbb{T}^1$ we have

$$u_\varepsilon^0(\rho_\varepsilon(\theta), \theta) = u_\varepsilon^0(\rho_\varepsilon^0, \theta) + (\rho_\varepsilon(\theta) - \rho_\varepsilon^0)\partial_r u_\varepsilon^0(\rho_\varepsilon^0, \theta) + \mathcal{O}((\rho_\varepsilon(\theta) - \rho_\varepsilon^0)^2).$$

Since the function u_ε^0 solves the Bernoulli problem (6), using the fact that ∂_r exactly corresponds to the normal derivative on the circle ∂A_ε^0, and using that for all $\theta \in \mathbb{T}^1$ we have $\rho_\varepsilon(\theta) - \rho_\varepsilon^0 = \mathcal{O}(\varepsilon)$, we obtain

$$u_\varepsilon^0(\rho_\varepsilon(\theta), \theta) = -\varepsilon B_0 - (\rho_\varepsilon(\theta) - \rho_\varepsilon^0)\lambda + \mathcal{O}(\varepsilon^2).$$

Choosing $B_0 = \lambda \rho_0 \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta)\, d\Theta$, we can then use the result (25) on the oscillating term $\widetilde{u}_\varepsilon^1$ to write

$$(29) \qquad\qquad v|_{\partial A_\varepsilon} = (\rho_\varepsilon - \rho_\varepsilon^0)\lambda + \mathcal{O}(\varepsilon^2).$$

• In the same way, we obtain the value of some derivative of v on ∂A_ε:

By definition of u_ε, and denoting by n_ε the outward unitary normal to the boundary ∂A_ε, we have

$$(30) \qquad\qquad \nabla u_\varepsilon|_{\partial A_\varepsilon} = -\lambda n_\varepsilon.$$

Using the Taylor formulae, we obtain

$$(31) \qquad \nabla u_\varepsilon^0|_{\partial A_\varepsilon} = \nabla u_\varepsilon^0|_{\partial A_\varepsilon^0} + (\rho_\varepsilon - \rho_\varepsilon^0)(\partial_r \nabla u_\varepsilon^0)|_{\partial A_\varepsilon^0} + \mathcal{O}((\rho_\varepsilon - \rho_\varepsilon^0)^2).$$

Due to the Bernoulli problem (6) satisfied by u_ε^0, we have

$$\nabla u_\varepsilon^0|_{\partial A_\varepsilon^0} = -\lambda n_\varepsilon^0,$$

where n_ε^0 denotes the outward unitary normal to the boundary ∂A_ε^0.

Moreover the expression of the laplacian operator in polar coordinates on the boundary ∂A_ε^0 reads:

$$\Delta u_\varepsilon^0 = \frac{1}{(\rho_\varepsilon^0)^2}\partial_\theta^2 u_\varepsilon^0 + \frac{1}{\rho_\varepsilon^0}\partial_{n_\varepsilon^0} u_\varepsilon^0 + \partial_{n_\varepsilon^0}^2 u_\varepsilon^0.$$

Since u_ε^0 solves the Bernoulli problem (6), we deduce that $(\partial_r \nabla u_\varepsilon^0)|_{\partial A_\varepsilon^0} = \dfrac{\lambda}{\rho_\varepsilon^0} n_\varepsilon^0$.

The equality (31) now reads

$$(32) \qquad\qquad \nabla u_\varepsilon^0|_{\partial A_\varepsilon} = -\lambda n_\varepsilon^0 + \frac{\rho_\varepsilon - \rho_\varepsilon^0}{\rho_\varepsilon^0}\lambda n_\varepsilon^0 + \mathcal{O}(\varepsilon^2).$$

Substracting (32) from (30), and noting that the oscillating contribution is not dominating (see the equation (26)) we get

$$\nabla v|_{\partial A_\varepsilon} = -\lambda(n_\varepsilon - n_\varepsilon^0) - \frac{\rho_\varepsilon - \rho_\varepsilon^0}{\rho_\varepsilon^0}\lambda n_\varepsilon^0 + \mathcal{O}(\varepsilon^2).$$

Taking the scalar product with $\widetilde{n} = (n_\varepsilon + n_\varepsilon^0)/\|n_\varepsilon + n_\varepsilon^0\|$ gives:

$$(33) \qquad\qquad \partial_{\widetilde{n}} v|_{\partial A_\varepsilon} = -\frac{\rho_\varepsilon - \rho_\varepsilon^0}{\rho_\varepsilon^0}\lambda \left(n_\varepsilon^0 \cdot \widetilde{n}\right) + \mathcal{O}(\varepsilon^2).$$

• We finally deduce the system satisfy by v:

$$(34) \qquad \begin{cases} \Delta v = f & \text{in } A_\varepsilon \setminus \overline{\Omega_\varepsilon}, \\ v = g & \text{on } \partial \Omega_\varepsilon, \\ \partial_{\widetilde{n}} v + \frac{1}{\rho_\varepsilon^0}\left(n_\varepsilon^0 \cdot \widetilde{n}\right) v = h & \text{on } \partial A_\varepsilon, \end{cases}$$

with $f = \mathcal{O}(\varepsilon^2)$, $g = \mathcal{O}(\varepsilon^2)$ and $h = \mathcal{O}(\varepsilon^2)$. The last condition is an oblique boundary condition obtained combining (29) and (33).

3.3. **Estimate of the error.**

3.3.1. *Bounds on a Laplace type problem.* In this section, we show that the regular function v satisfying (34) on the regular domain $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$ satisfies $v = \mathcal{O}(\varepsilon^2)$.

Let $\gamma = \frac{n_\varepsilon^0 \cdot \tilde{n}}{\rho_\varepsilon^0}$. It is clear that $\gamma > \sqrt{2}/(2\rho_\varepsilon^0) > \sqrt{2}/(2\rho_0) > 0$, thus one can choose a positive number R which does not depend on ε such that the function $\varphi(x,y) = R^2 - \frac{1}{4}(x^2 + y^2)$ satisfies:

$$(35) \qquad \left\{ \begin{array}{rcll} -\Delta\varphi & = & 1 & \text{in } A_\varepsilon \setminus \overline{\Omega_\varepsilon}, \\ \varphi & \geq & 1 & \text{on } \partial\Omega_\varepsilon, \\ \alpha\partial_{n_\varepsilon}\varphi + \beta\partial_{\tau_\varepsilon}\varphi + \gamma\varphi & \geq & 1 & \text{on } \partial A_\varepsilon, \end{array} \right.$$

where the coefficients $\alpha = \tilde{n} \cdot n_\varepsilon$ and $\beta = \tilde{n} - \alpha n_\varepsilon \in \mathbb{R}$ are chosen so that the boundary condition on ∂A_ε corresponds to the boundary condition of system (34), $\partial_{\tau_\varepsilon}\varphi \in \mathbb{R}$ denoting the tangential derivative on ∂A_ε.
Note that $\sqrt{2}/2 < \alpha \leq 1$.
Consequently the function $V = \max\{|f|_\infty, |g|_\infty, |h|_\infty\}\varphi - v$ is a regular function which satisfies

$$(36) \qquad \left\{ \begin{array}{rcll} -\Delta V & \geq & 0 & \text{in } A_\varepsilon \setminus \overline{\Omega_\varepsilon}, \\ V & \geq & 0 & \text{on } \partial\Omega_\varepsilon, \\ \alpha\partial_{n_\varepsilon}V + \beta\cdot\partial_{\tau_\varepsilon}V + \gamma V & \geq & 0 & \text{on } \partial A_\varepsilon. \end{array} \right.$$

Moreover, the domain $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$ is regular since, by hypothesis, Ω_ε is regular and since the domain A_ε is regular too (see [3]). This allows us to deduce the following result:

Lemma 1. *The function V is nonnegative on $A_\varepsilon \setminus \overline{\Omega_\varepsilon}$.*

Proof of Lemma 1 - Since $\Delta V \leq 0$ the minimum of V in $\overline{A_\varepsilon \setminus \overline{\Omega_\varepsilon}}$ is achieved on its boundary $\partial(A_\varepsilon \setminus \overline{\Omega_\varepsilon}) = \partial A_\varepsilon \cup \partial\Omega_\varepsilon$. If it is achieved on $\partial\Omega_\varepsilon$, then the proof is completed. If it is achieved on $y \in \partial A_\varepsilon$, then, since V is regular, we have $\partial_{n_\varepsilon}V(y) \leq 0$ and $\partial_{\tau_\varepsilon}V(y) = 0$. Since $\alpha \geq 0$ we deduce that $V(y) = \gamma^{-1}\left(h(y) - \alpha(y)\partial_{n_\varepsilon}V(y) - \beta(y)\cdot\partial_{\tau_\varepsilon}V(y)\right) \geq 0$.

Lemma 1 implies that $v \leq \max\{|f|_\infty, |g|_\infty, |h|_\infty\}|\varphi|_\infty$.
In the same way, using $\tilde{V} = -\max\{|f|_\infty, |g|_\infty, |h|_\infty\}\varphi - v$ instead of V we show that $\tilde{V} \leq 0$. We conclude that

$$(37) \qquad |v|_\infty \leq \max\{|f|_\infty, |g|_\infty, |h|_\infty\}|\varphi|_\infty = \mathcal{O}(\varepsilon^2).$$

Due to the equation (29) we deduce that $\rho_\varepsilon - \rho_\varepsilon^0 = \mathcal{O}(\varepsilon^2)$, which is equivalent to $\mathcal{D}_\mathcal{H}(A_\varepsilon^0, A_\varepsilon) = \mathcal{O}(\varepsilon^2)$. Theorem 1 is proved.

4. NUMERICAL RESULTS

This section is devoted to numerical results to check the conclusion of Theorem 1, first by comparing the solution of (2) and (6) and then by observing that the roughness on the free boundary are much smaller than those of the fixed boundary.

Two kinds of perturbations have been considered, which are the 2π-periodic functions denoted by h_1 and h_2 defined on $(0, 2\pi)$ by:

- $h_1(\alpha) = 1 - \cos(\alpha)$,
- $h_2(\alpha) = \pi - |\alpha - \pi|$.

4.1. **Numerical approximation for the oscillating problem** (6)**.** In this section, we effectively compute the value of the constant B_0 which appears in the Bernoulli problem (6). In practice, we need to solve the problem (9) which is defined in an infinite domain ω, and then evaluate the integral $\int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, d\Theta$ to deduce the value of the constant B_0 *via* the formulae (10). For a numerical approach we introduce the "truncated" cell domain

$$(38) \qquad \omega_M = \big\{ (R, \Theta) \in \mathbb{R}_+ \times \mathbb{T}^1 \; ; \; M > R > -h(\Theta) \big\},$$

where M has been chosen large, and solve the Laplace problem: Find a function $\widetilde{u}_1^M$ defined on ω_M, periodic with respect to Θ and such that

$$(39) \qquad \begin{cases} \widetilde{\Delta} \widetilde{u}_1^M &=& 0 & \text{in } \omega_M, \\ \widetilde{u}_1^M(-h(\Theta), \Theta) &=& -h(\Theta) & \text{for } \Theta \in \mathbb{T}^1, \\ \partial_R \widetilde{u}_1^M(M, \Theta) &=& 0 & \text{for } \Theta \in \mathbb{T}^1. \end{cases}$$

The solution of this problem being exponentially close to the solution of (9) for large M, we have:

$$(40) \qquad \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, d\Theta \approx \int_{\mathbb{T}^1} \widetilde{u}_1^M(0, \Theta) \, d\Theta.$$

The computations of these integrals were performed with the FreeFem++ program (This software, see http://www.freefem.org/ff++ is based on weak formulation of the problem and finite elements method). We choose $M = 6$ and the mesh is composed of about $2 \cdot 10^6$ triangles. These computations give:

- $\int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, d\Theta \approx -0.58738$ for the shape $h_1(\alpha) = 1 - \cos(\alpha)$,

- $\int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, d\Theta \approx -0.87754$ for the shape $h_2(\alpha) = \pi - |\alpha - \pi|$.

4.2. **Comparison of problems** (2) **and** (6)**.** The aim of these first tests is to show that the solution of (6) approaches the solution of (2) at second order with respect to ε. Note that all these tests use the algorithm presented in [8] to solve the Bernoulli problem (2).

Here, we take $\lambda = 2e^{-1/2}$ so that the domain solution without roughness is a disc of radius $\rho_0 = e^{1/2}$. Thus, we have $\lambda \rho_0 = 2$, and we then:

- $B_0 = \lambda \rho_0 \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, d\Theta \approx -1.17476$ for the shape $h_1(\alpha) = 1 - \cos(\alpha)$,

- $B_0 = \lambda \rho_0 \int_{\mathbb{T}^1} \widetilde{u}_1(0, \Theta) \, d\Theta \approx -1.75508$ for the shape $h_2(\alpha) = \pi - |\alpha - \pi|$.

We check that

$$\frac{\mathcal{D}_{\mathcal{H}}(A_\varepsilon, A_\varepsilon^0)}{\varepsilon^2} \text{ is bounded}$$

with respect to ε according to Theorem 1: The computed values are reported in Table 1 and 2. On coarse meshes (see the two first lines of tables 1 and 2), some grid effects deteriorate the quality of numerical results for small ε due to the small size of roughness.

The numerical simulation on the finer mesh (see last line of tables 1 and 2) seems accurate enough to confirm the conclusion of Theorem 1.

	$\varepsilon = 0.1$	$\varepsilon = 0.05$	$\varepsilon = 0.025$
$\delta x = 6 \times 10^{-3}$	0.1524	0.0186	0.2832
$\delta x = 3 \times 10^{-3}$	0.1551	0.0238	0.0451

TABLE 2. Values of $\dfrac{\mathcal{D}_{\mathcal{H}}(A_\varepsilon, A_\varepsilon^0)}{\varepsilon^2}$ for the perturbation h_2.

4.3. **The oscillations of the free boundary.** We now present some figures to show the oscillations observed on the computed solution. We plot on Figure 1 the given and solution domains corresponding to the first test case of the previous section. As indicated by table 1, we just observe that the solution domain is very close to a disc.

FIGURE 1. Given domain and its associated solution for the perturbation h_1 ($\lambda = 2\mathrm{e}^{-1/2}$, $\rho_0 = \mathrm{e}^{1/2}$, $\varepsilon = 0.1$).

In order to observe small oscillations on the solution domains, we changed the value of λ so that $\lambda = 8\mathrm{e}^{-1/8}$, and then $\rho_0 = \mathrm{e}^{1/8}$ which means that the solution domain comes closer to the given domain which is (intuitively) a better situation to observe oscillations. The function h corresponding to the given domain is the function h_1 of section 4.2, and we take $\delta_x = 6 \times 10^{-3}$. On Figure 2, for $\varepsilon = 0.1$, we can observe that the solution domain is not a circle and that some small oscillations seem to be induced by the oscillations of the given domain Ω_ε.

On Figure 3, for a smaller value of ε, we need to zoom on a part of the picture to observe the same behaviour of the solution domain.

On Figure 4, the value of ε is so small that the oscillation on the solution domain can no more be observed even on the zoomed figure. These tests also confirm the qualitative conclusion of Theorem 1.

5. CONCLUSION

In this work, we have given a result concerning the solution of the free boundary Bernoulli problem with a given rough domain. In the case where the given domain is a disc with roughness, we show that the solution is close to a disc whose radius can be computed explicitly
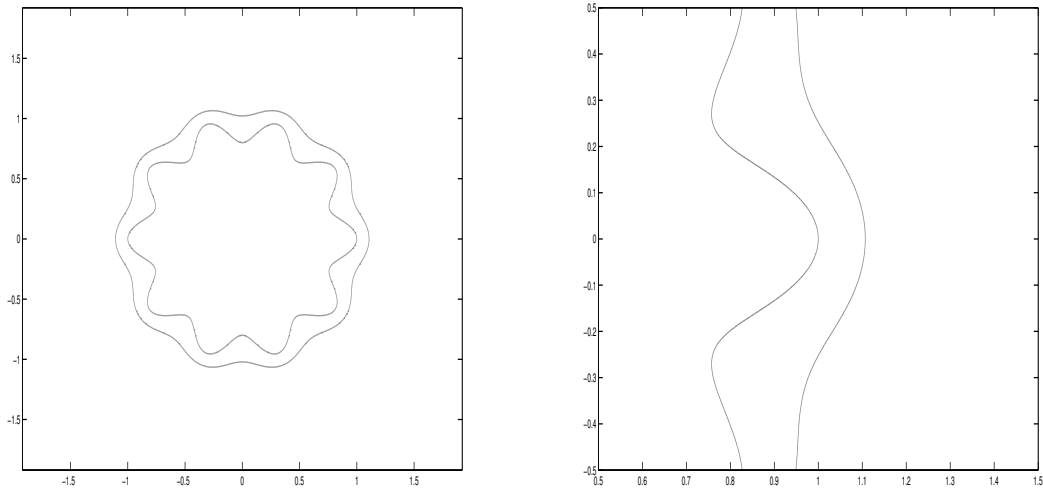

FIGURE 2. Given domain and its associated solution for the perturbation h_1 with $\lambda = 8\,\mathrm{e}^{-1/8}$, $\rho_0 = \mathrm{e}^{1/8}$, $\varepsilon = 0.1$.

FIGURE 3. Given domain and its associated solution for the perturbation h_1 with $\lambda = 8\,\mathrm{e}^{-1/8}$, $\rho_0 = \mathrm{e}^{1/8}$, $\varepsilon = 0.05$.

and converges to this disc at second order in ε, ε being the size of the roughness as well as the inverse of their wave length.

This work can be pursued in many directions: the technique used here could allow to get a better estimate of the solution (at third or further order in ε). Moreover, It might be interesting to consider the same kind of study for more complex domain (not only a perturbation of a disc), or in the case of higher dimensions. Another complexity can be introduced considering some nonlinear Bernoulli problem such that the classical p-Laplacian problem.

APPENDIX A. METRICS

We state here some equivalence results between distances used for interfaces.

Let $0 < \delta < M$ be given, we consider the set of curves of $\mathbb{R}^2$:

$$\mathcal{K} = \left\{ \Gamma = \partial\Omega \text{ where } \Omega \subset \mathcal{B}(0, M) \text{ is a starlike domain with respect to all points in } \mathcal{B}(0, \delta) \right\}.$$

Note that, for all $\Gamma \in \mathcal{K}$, there exists a unique parametrization $f_\Gamma : \mathbb{T}^1 \to \mathbb{R}_+$ of Γ in polar coordinates, which then satisfies:

$$\Gamma = \{ (f_\Gamma(\theta), \theta) \in \mathbb{R}^2, \theta \in \mathbb{T}^1 \}.$$

We define a first distance on the set $\mathcal{K}$ based on this parametrization:

$$d_1(\Gamma_1, \Gamma_2) = \| f_{\Gamma_2} - f_{\Gamma_1} \|_{L^\infty}.$$

We recall the definition of the metric defined in [3] *(which is denoted by Δ in [3])*:

$$d_2(\Gamma_1, \Gamma_2) = \sup\{ |\ln(\lambda)|, \lambda \in \mathbb{R}_+ \ ; \ \lambda\Gamma_1 \cap \Gamma_2 \neq \emptyset \}.$$

We also recall the definition of the classical Hausdorff distance *(denoted here $\mathcal{D}_\mathcal{H}$)*:

$$\mathcal{D}_\mathcal{H}(\Gamma_1, \Gamma_2) = \max\left(\sup\{ d(x, \Gamma_2), x \in \Gamma_1 \}, \sup\{ d(x, \Gamma_1), x \in \Gamma_2 \} \right)$$

where d is the classical (euclidian) distance.

Proposition 5. *The distances d_1, d_2 and $\mathcal{D}_\mathcal{H}$ are equivalent on $\mathcal{K}$.*

Proof: Let us first remark that, for all Γ_1 and Γ_2 in $\mathcal{K}$, we have:

$$d_1(\Gamma_1, \Gamma_2) \leq M - \delta,$$

$$d_2(\Gamma_1, \Gamma_2) \leq \ln(M/\delta),$$

$$\mathcal{D}_\mathcal{H}(\Gamma_1, \Gamma_2) \leq M - \delta.$$

- **Step** 1 - We prove that for all $(\Gamma_1, \Gamma_2) \in \mathcal{K}^2$ we have $d_1(\Gamma_1, \Gamma_2) \leq \frac{M^2}{\delta} d_2(\Gamma_1, \Gamma_2)$.
  Without loss of generality, we can assume that there exists $\theta_0 \in \mathbb{T}^1$ such that:
  $$f_{\Gamma_2}(\theta_0) = f_{\Gamma_1}(\theta_0) + d_1(\Gamma_1, \Gamma_2).$$
  We have $f_{\Gamma_2}(\theta_0) = \lambda f_{\Gamma_1}(\theta_0)$ with $\lambda = \dfrac{f_{\Gamma_1}(\theta_0) + d_1(\Gamma_1, \Gamma_2)}{f_{\Gamma_1}(\theta_0)}$, and then $\lambda \Gamma_1 \cap \Gamma_2 \neq \emptyset$
  for this choice of λ. We then deduce:
  $$\ln\left(\frac{f_{\Gamma_1}(\theta_0) + d_1(\Gamma_1, \Gamma_2)}{f_{\Gamma_1}(\theta_0)}\right) \leq d_2(\Gamma_1, \Gamma_2)$$
  and then:
  $$d_1(\Gamma_1, \Gamma_2) \leq f_{\Gamma_1}(\theta_0)\left(\exp(d_2(\Gamma_1, \Gamma_2)) - 1\right)$$
  Using $f_{\Gamma_1}(\theta_0) \leq M$ and $\exp(d_2(\Gamma_1, \Gamma_2)) - 1 \leq d_2(\Gamma_1, \Gamma_2)\exp(d_2(\Gamma_1, \Gamma_2)) \leq d_2(\Gamma_1, \Gamma_2) \times (M/\delta)$, we get the desired result.
- **Step** 2 - We prove that for all $(\Gamma_1, \Gamma_2) \in \mathcal{K}^2$ we have $d_2(\Gamma_1, \Gamma_2) \leq \frac{M}{\delta^2} \mathcal{D}_{\mathcal{H}}(\Gamma_1, \Gamma_2)$.
  Without loss of generality, we can assume that there exists $\theta_0 \in \mathbb{T}^1$ such that $f_{\Gamma_2}(\theta_0) = \exp(d_2(\Gamma_1, \Gamma_2))f_{\Gamma_1}(\theta_0)$. The bounded domain Ω_2 (such that $\Gamma_2 = \partial\Omega_2$) being starlike with respect to all points in $\mathcal{B}(0, \delta)$, it contains the domain $\mathcal{T} = \cup_{m \in \mathcal{B}(0,\delta)}[m, f_{\Gamma_2}(\theta_0)]$, where $[m, f_{\Gamma_2}(\theta_0)]$ denotes the line delimited by these two points. Note that $\mathcal{T}$ is actually the union of a triangle and $\mathcal{B}(0, \delta)$.
  Simple geometric arguments shows that
  $$d(f_{\Gamma_1}(\theta_0), \partial\Gamma_2) \geq d(f_{\Gamma_1}(\theta_0), \partial\mathcal{T})$$
  and
  $$d(f_{\Gamma_1}(\theta_0), \partial\mathcal{T}) = \delta \frac{f_{\Gamma_2}(\theta_0) - f_{\Gamma_1}(\theta_0)}{f_{\Gamma_2}(\theta_0)}.$$
  We then get *(denoting $d_2 = d_2(\Gamma_1, \Gamma_2)$)*:
  $$d_2 \leq \exp(d_2) - 1 \leq \frac{\exp(d_2) - 1}{\exp(d_2)} \times \exp(d_2) \leq \frac{f_{\Gamma_2}(\theta_0) - f_{\Gamma_1}(\theta_0)}{f_{\Gamma_2}(\theta_0)} \times \exp(d_2)$$
  $$\leq \frac{f_{\Gamma_2}(\theta_0) - f_{\Gamma_1}(\theta_0)}{f_{\Gamma_2}(\theta_0)} \times \frac{M}{\delta} \leq \frac{d(f_{\Gamma_1}(\theta_0), \partial\Gamma_2)}{\delta} \times \frac{M}{\delta} \leq \frac{M}{\delta^2}\mathcal{D}_{\mathcal{H}}(\Gamma_1, \Gamma_2)$$
  which gives the desired result.
- **Step** 3 - We prove that for all $(\Gamma_1, \Gamma_2) \in \mathcal{K}^2$ we have $\mathcal{D}_{\mathcal{H}}(\Gamma_1, \Gamma_2) \leq d_1(\Gamma_1, \Gamma_2)$.
  Let $x \in \Gamma_1$ such that $d(x, \Gamma_2) = \mathcal{D}_{\mathcal{H}}(\Gamma_1, \Gamma_2)$. Noting $x = (f_{\Gamma_1}(\theta), \theta)$, $\theta \in \mathbb{T}^1$, it is clear that $|f_{\Gamma_2}(\theta) - f_{\Gamma_1}(\theta)| \geq d(x, \Gamma_2)$ which proves the desired result.
