HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

VISCOELASTIC FLOWS IN A ROUGH CHANNEL: A MULTISCALE ANALYSIS

LAURENT CHUPIN AND SÉBASTIEN MARTIN

ABSTRACT. In this paper, we consider *viscoelastic* flows in a rough domain (with typical roughness patterns of size $\varepsilon \ll 1$). We present and rigorously justify an asymptotic expansion with respect to ε , at any order, based upon the definition of elementary problems: Oldroyd-type problems at the global scale defined on a smoothed domain and boundary-layer corrector problems. The resulting analysis guarantees optimality with respect to the truncation error.

1. INTRODUCTION

Many studies investigate the effect of wall roughness on Newtonian flows. In 1827, C. L. Navier [26] was one of the first scientists to note that the roughness could drag a fluid. Since then, numerous studies attempted to prove mathematical results in this direction, see for instance the works of W. Jäger and A. Mikelić [20], Y. Amirat and co-authors [3, 4] and more recently the works of D. Bresch and V. Milisic [12]. Note that all these works formulate the roughness using a periodic function (whose amplitude and period are supposed to be small). In a context of more general “roughness” patterns, there exists similar recent results, see [6, 19]. All the previous work deal with a *Newtonian* flow, for which the Stokes or Navier-Stokes equations are classically considered.

Much literature research has been devoted to non-Newtonian fluids, in both mathematical aspects and applications. It is well known that numerous biological fluids, blood or physiological secretions like tears or synovial fluids, show these non-Newtonian characteristics. In engineering applications people are interested in controlling the flows characteristics to suit various requirements such as maintaining the fluid qualities in a wide range of temperatures and stresses. Introduction of additives lead to non-Newtonian behavior of the modern lubricants for instance. Another application domain is linked to polymers, whose non-Newtonian characteristics appear in a wide range of applications such as the molding or injection processes. Some particular classes of non-Newtonian models have often been considered. This includes the Bingham flow or the quasi-Newtonian fluids (Carreau’s law [13, 22], the power law or Williamson’s law, in which various stress-velocity relations are chosen [33] or [8, 10] for mathematical aspects) and also micropolar ones [25]. These models, however, consider the fluid as viscous and elasticity effects are neglected. The introduction of such a viscoelastic behavior is primarily described by the Weissenberg number, denoted We which can be viewed as a measure of the elasticity of the fluid and is related to its characteristic relaxation time. One of the laws which seems the most able to describe viscoelastic flows is the Oldroyd model. This model is based on a constitutive equation which is an interpolation between

purely viscous and purely elastic behaviors, thus introducing a supplementary parameter r which describes the relative proportion of both behaviors (the solvent to solute ratio). Considering the Oldroyd model [27], the momentum, continuity and constitutive equations for an incompressible flow of such a non-Newtonian fluid are, respectively,

$$(1) \quad \rho \left(\partial_t u + u \cdot \nabla u \right) - \eta(1-r)\Delta u + \nabla p - \operatorname{div} \sigma = 0,$$

$$(2) \quad \operatorname{div} u = 0,$$

$$(3) \quad \lambda \left(\partial_t \sigma + u \cdot \nabla \sigma + g_a(\nabla u, \sigma) \right) + \sigma - \delta \Delta \sigma = 2\eta r \mathbb{D}(u).$$

In these equations, ρ , η and λ are positive constants which respectively correspond to the fluid density, the fluid viscosity and the relaxation time. It is important to notice the presence of a term $\delta \Delta \sigma$, $\delta > 0$ corresponding to a spatial diffusion of the polymeric stresses. Usually (*i.e.* for the Oldroyd model) this term is deleted, but it can be physically justified: physical effects that can contribute to the diffusive process include hydrodynamic interactions [18], particle diffusion [7] and semiflexibility of polymer blends [23]. Thus, the diffusive Oldroyd models have been the subject of intense studies related to the understanding of shear-banded flows or phase coexistence, see [28, 32, 29, 24, 30] and, as a consequence, the investigation of the mathematical properties of the diffusive model has gained an increasing interest recently [18, 5, 17, 16].

Equations (1)–(3) make up a system of 10 scalar equations with 10 unknowns: the lubricant velocity vector $u = (u_i)_{1 \leq i \leq 3}$, the pressure p and the extra-stress symmetric tensor $\sigma = (\sigma_{i,j})_{1 \leq i,j \leq 3}$. The bilinear application g_a , $-1 \leq a \leq 1$, is defined by

$$g_a(\nabla u, \sigma) = \sigma \cdot \mathbb{W}(u) - \mathbb{W}(u) \cdot \sigma - a(\sigma \cdot \mathbb{D}(u) + \mathbb{D}(u) \cdot \sigma)$$

where $\mathbb{D}(u)$ and $\mathbb{W}(u)$ are respectively the symmetric and skew-symmetric parts of the velocity gradient ∇u . Usually, $\mathbb{D}(u)$ is called the rate of strain tensor and $\mathbb{W}(u)$ is called the vorticity tensor. Notice that the parameter a is considered to interpolate between upper convected ($a = 1$) and lower convective derivatives ($a = -1$), the case $a = 0$ being the corotational case [21]. Note that taking $r = 1$ allows us to recover various forms of the generalized Maxwell model. Conversely, a Newtonian flow is described by choosing $r = 0$.

In this paper, we focus on *viscoelastic* flows in a rough domain (with typical roughness patterns of size $\varepsilon \ll 1$). We present and rigorously justify an asymptotic expansion with respect to ε . The development is done at any order, so that we are guaranteed to be optimal with respect to the truncation error. We also highlight the particular effects of roughness.

Several relevant questions are not addressed in this article. First, recent works on random roughness, see [6, 19], could make us think that our results can be extended to more general cases of roughness. In fact, the construction of our development strongly depends on the behavior of solutions of the Stokes equation on a half-space, whose lower boundary is periodic. The behavior of such solutions must be sufficiently decreasing at infinity to justify our development. Unfortunately, it seems that this decrease is only logarithmic in the case of a random boundary (while it is exponential in our periodic case). Second, another task related to the regularity

of the roughness patterns is not addressed in this paper: what is the behavior of the solution when the patterns are not Lipschitz continuous? In particular, what is the influence of roughness jump discontinuities over the flow? Finally, the choice to make appear a spatial diffusion ($\delta > 0$) in the Oldroyd model could be argued. From a mathematical point of view, it is clearly an advantage since we know that such diffusion allows to have solutions to the initial problem (1)–(3). Nevertheless, even if we admit the existence of a smooth solution to the initial problem without diffusion ($\delta = 0$), the development proposed with respect to the roughness parameter ε seems to be unsuitable.

The paper is composed of five sections. In Section 2, we introduce the diffusive Oldroyd model, we precisely describe the roughness geometry and we recall a fundamental result: there exists a solution (u, p, σ) to the model. In Section 3 we introduce the ansatz, which is a formal asymptotic expansion of the solution (u, p, σ) with respect to the roughness parameter $\varepsilon \ll 1$. By identifying the powers of ε in such a development, we obtain some elementary problems at any order. Section 4 is devoted to the mathematical study of these elementary problems: well-posedness and properties. Section 5 provides a rigorous justification of the asymptotic expansion by analyzing the remainder and deriving error estimates. In Section 6, we show that it is possible to effectively determine all the contributions of the ansatz. We will notice that regarding each elementary problem and their overlaps, this crucial result is not obvious: we prove that the solution of each problem can be built using the only previous elementary solutions.

2. THE DIFFUSIVE OLDROYD SYSTEM IN A ROUGH CHANNEL: STATEMENT OF THE PROBLEM

As a matter of fact, the derivation of reduced models is crucial if one aims at performing numerical simulations of the flow. However, roughness patterns lead to a sharp increase of the computational costs because the mesh of the domain has to be built according to the constraints defined by the roughness patterns. In order to avoid such a costly procedure, reduced models can be defined by considering the fluid flow in the smooth domain (therefore avoiding heavy costs in terms of numerical computations by using coarse meshes) and adding a so-called boundary layer correction which takes into account the influence of the roughness pattern. More precisely, for a *Newtonian* flow, we can proceed as follows (see [26, 1, 20, 12], and also [19, 6] for random roughness patterns):

- *at order 0*: assume that u is the velocity fluid associated to the rough domain ω_ε and u_0 is the velocity fluid associated to the smooth domain (i.e. the domain has been truncated by considering a *flat* boundary instead of the oscillating one and imposing the Dirichlet condition on the smooth boundary), see Fig. 1. Then one has

$$\|u - u_0\|_{L^2(\omega_\varepsilon)} \lesssim \varepsilon \quad \text{and} \quad \|u - u_0\|_{H^1(\omega_\varepsilon)} \lesssim \sqrt{\varepsilon}.$$

- *at order 1*: in order to counterbalance the error introduced by the truncation of the domain, it is possible to introduce a corrector term which leads to the justification of wall laws. By considering the smooth domain with a slip

condition defined as

$$\begin{cases} u^{(1)} = \alpha_{11} \partial_y u^{(1)} + \alpha_{12} \partial_y u^{(2)} \\ u^{(2)} = \alpha_{21} \partial_y u^{(1)} + \alpha_{22} \partial_y u^{(2)} \\ u^{(3)} = 0 \end{cases}$$

on the smooth boundary (the reals $\alpha_{i,j}$ being coefficients depending on the roughness shape), a velocity field \bar{u} is defined, leading to a refinement of the approximation. For instance we have (see [20])

$$\|u - \bar{u}\|_{L^2(\omega_\varepsilon)} \lesssim \varepsilon^{3/2} \quad \text{and} \quad \|u - \bar{u}\|_{H^1(\omega_\varepsilon)} \lesssim \varepsilon.$$

FIGURE 1. a) Rough domain. b) *Flattened* domain: the rough boundary has been truncated by a smooth one. c) Boundary layer domain corresponding to a focus on the vicinity of the rough periodic boundary.

For a non-Newtonian flow of the viscoelastic type, we aim at describing the roughness effects *extensively* in the following sense:

- build an asymptotic expansion based upon elementary solutions (i.e. solutions of problems defined on smooth domains, thus avoiding complex geometries) ;
- prove in a rigorous way that the asymptotic expansion is valid at any order ;
- define an algorithm associated to an efficient numerical procedure.

Therefore we consider the Navier-Stokes equations with the Oldroyd model in a rough channel. Consider the domain

$$\omega_\varepsilon := \left\{ (x, y) \in \mathbb{T}^d \times \mathbb{R}, -\varepsilon H\left(\frac{x}{\varepsilon}\right) < y < 1 \right\},$$

where \mathbb{T}^d is the d -dimensional torus, $d = 1$ or $d = 2$, and H a smooth periodic and positive function. The boundary ω_ε is denoted γ_ε and it is composed of two connex components: The upper *smooth* boundary $\gamma^+ = \mathbb{T}^d \times \{1\}$ and the upper *highly oscillating* boundary which is denoted γ_ε^- , see Fig. 2.

Then we consider the following set of equations:

$$(4) \quad \begin{cases} \operatorname{Re}(u \cdot \nabla u) - (1-r)\Delta u + \nabla p = \operatorname{div} \sigma + f, & \text{in } \omega_\varepsilon, \\ \operatorname{div} u = 0, & \text{in } \omega_\varepsilon, \\ \operatorname{We}(u \cdot \nabla \sigma + g_a(\nabla u, \sigma)) + \sigma - \mathbb{D} \Delta \sigma = 2r\mathbb{D}(u), & \text{in } \omega_\varepsilon, \\ u = 0, & \text{on } \gamma_\varepsilon, \\ \mathbb{D} \partial_n \sigma = 0, & \text{on } \gamma_\varepsilon. \end{cases}$$

FIGURE 2. Channel with oscillating boundary.

This system is the non-dimensional version of the system (1)–(3). We have introduced the Reynolds number Re , the Weissenberg number We , a relaxation parameter $r \in [0, 1]$ and the diffusion coefficient D .

In the next sections, we aim at describing the structure of the solution (u, p) with respect to the roughness number ε . Before entering into this description, let us recall the main mathematical results related to the stationary diffusive Oldroyd model. The problem defined in a strong form can be associated to a variational formulation. Then we have (see [16] for details):

Theorem 1. *Let $f \in H^{-1}(\omega_\varepsilon)^3$. Let $\text{Re} \geq 0$, $\text{We} \geq 0$, $0 < r < 1$, $-1 \leq a \leq 1$ and $D > 0$. Let us introduce the following constants:*

$$C_{(\text{I})} := \frac{8|a|C_{\omega_\varepsilon}^2 \text{We} \|f\|_{H^{-1}}}{\min(1-r, D)^2}, \quad C_{(\text{II})} := \frac{\sqrt{2r} \min(1-r, D)}{4|a|C_{\omega_\varepsilon}^2 \text{We}} (1 - \sqrt{1 - C_{(\text{I})}}),$$

where C_{ω_ε} is a constant which only depends on the domain ω_ε .

- Existence. *If $C_{(\text{I})} \leq 1$ then, the problem (4) admits a variational solution (u, σ) which satisfies*

$$2r \|\nabla u\|_{L^2}^2 + \|\sigma\|_{H^1}^2 \leq C_{(\text{II})}^2.$$

Moreover there exists a pressure field $p \in L^2(\Omega)$ such that (u, p) satisfies the first equation of the problem (4) in the sense of distributions.

- Uniqueness. *The variational formulation of the problem (4) admits at most one solution if one of the following conditions is satisfied:*
 - a) $\|f\|_{H^{-1}}$ is small enough;
 - b) Re and We are small enough.
- Regularity. *If f is regular then the variational solution is regular and satisfies the problem (4) in a classical sense.*

Let us remark that the corotationnal case (namely $a = 0$) allows us to get rid of the smallness assumption on the data.

3. ASYMPTOTIC EXPANSION

3.1. Main ideas: ansatz. Let us describe the structure of the solution by using a suitable *ansatz*:

$$\left\{ \begin{array}{l} u(x, y) = u_0(x, y) + \varepsilon U_1\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) + \varepsilon u_1(x, y) + \varepsilon^2 U_2\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) + \dots \\ \quad = \sum_{k=0}^{+\infty} \varepsilon^k \left(u_k(x, y) + U_k\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) \right), \\ p(x, y) = p_0(x, y) + P_1\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) + \varepsilon p_1(x, y) + \varepsilon P_2\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) + \dots \\ \quad = \sum_{k=0}^{+\infty} \varepsilon^k \left(p_k(x, y) + P_{k+1}\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) \right), \\ \sigma(x, y) = \sigma_0(x, y) + \varepsilon \Sigma_1\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) + \varepsilon \sigma_1(x, y) + \varepsilon^2 \Sigma_2\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) + \dots \\ \quad = \sum_{k=0}^{+\infty} \varepsilon^k \left(\sigma_k(x, y) + \Sigma_k\left(x, \frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) \right). \end{array} \right.$$

The definition of the asymptotic expansion has to be completed by the description of the problems satisfied by the *elementary solutions*. Then another task consists in showing that each elementary problem is well posed. The final task consists in showing that the level of truncation in the asymptotic expansion is directly related to the quality of the approximation of the exact solution.

In order to identify the *elementary problems* satisfied by the *elementary solutions*, we proceed as follows:

- (1) separation of the macroscopic variables (x, y) and the microscopic ones which will be denoted $(X, Y) = \left(\frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right)$;
- (2) identification of terms with the same order with respect to ε in the equations ;
- (3) identification of terms with the same order with respect to ε in the boundary conditions.

Notation 1. We will use lowercase letters to denote elements corresponding to the real physical domain $(x, u, \sigma, \omega\dots)$ and uppercase letters for all that concerns the microscopic field $(X, U, \Sigma, \Omega\dots)$.

To complete this subsection, and before getting into the details, let us explain the way the asymptotic expansion has been built: at main order, the fluid flow is governed by a classical viscoelastic model with boundary conditions located at the flat bottom $y = 0$ (definition of (u_0, p_0, σ_0)). But, of course, the boundary layer has been omitted and, in fact, the boundary condition should have been imposed on the oscillating boundary instead of the smooth one ; it can be shown that the resulting error is of order ε (the size of the boundary layer) and, therefore, a so-called *boundary layer correction* is introduced in order to counterbalance the mentioned boundary value default (definition of (U_1, P_1, Σ_1)). Now if we analyze the approximate solution defined as $(u_0 + \varepsilon U_1, p_0 + P_1, \sigma_0 + \varepsilon \Sigma_1)$, the equations in the domain and the boundary condition at the oscillating boundary are satisfied by means of construction ; unfortunately, the boundary condition on the upper boundary is not satisfied by the approximate solution because of the behavior of the boundary layer corrector at infinity. However the error is of order ε and it is possible to build a solution on the smooth domain (definition of (u_1, p_1, σ_1)) which counterbalances this

boundary value default on the upper boundary. Again, at his step, by considering the smooth domain only (in particular, homogeneous boundary conditions are considered at the lower *smooth* boundary), the boundary layer has been omitted and, in fact, the boundary condition should have been imposed on the oscillating boundary ; the resulting error is *now* of order ε^2 . Thus, if we compare $(u_\varepsilon, p_\varepsilon, \sigma_\varepsilon) - (u_0, p_0, \sigma_0)$ and $(u_\varepsilon, p_\varepsilon, \sigma_\varepsilon) - (u_0 + \varepsilon U_1 + \varepsilon u_1, p_0 + P_1 + \varepsilon p_1, \sigma_0 + \varepsilon \Sigma_1 + \varepsilon \sigma_1)$, the error has been decreased by an order of magnitude and, besides, the same procedure can be applied by introducing a boundary layer correction which counterbalances the boundary value default of order ε^2 at the oscillating boundary.

In a more general way, the boundary value default introduced at the oscillating boundary can be counterbalanced by a boundary layer correction ; the resulting boundary value default at the upper boundary can be counterbalanced by a viscoelastic flow defined in the *smooth* domain. Through this procedure, the resulting approximation satisfies the equations in the domain, the boundary condition at the upper boundary and the error on the boundary condition on the oscillating boundary has been decreased by an order of magnitude.

Let us define the two rescaled sub-domains. As a matter of fact, the main flow is defined on the smooth domain whereas, due to the consideration of the roughness patterns, the boundary layer is rescaled by the homothetic transformation $(X, Y) := (\frac{x}{\varepsilon}, \frac{y}{\varepsilon})$.

Definition 1. *The smooth domain is defined by*

$$\omega_0 := \{(x, y) \in \mathbb{T}^d \times \mathbb{R}, \quad 0 < y < 1\}.$$

The upper boundary equals γ^+ and the lower boundary corresponds to γ_0^- . The normal outward unit vector the lower (resp. upper) boundary is $n = (0, -1)$ (resp. $(0, 1)$) on γ_0^- (resp. γ^+).

Definition 2. *The boundary layer domain is defined by*

$$\Omega = \{(X, Y) \in \mathbb{T}^d \times \mathbb{R}, \quad -H(X) < Y\}.$$

The boundary $\{(X, Y) \in \mathbb{T}^d \times \mathbb{R}, \quad Y = -H(X)\}$ is denoted Γ . We denote by $N := -(\nabla H, 1)$ the outward vector to the lower boundary. Note that N is not a unit vector.

Notation 2. *The usual notation for classical operator of derivation are ∇ , div and Δ . The problems considered in this paper make appear two kinds of functions: the first ones, like the velocity u , which only depend on the macroscopic variables (x, y) , and the others, like the velocity U which depend on (x, X, Y) . In the first case the classical operators are defined as usual, for instance*

$$\Delta u = \sum_{\ell=1}^d \partial_{x_\ell}^2 u + \partial_y^2 u.$$

In the case of function depending on (x, X, Y) , the notations are the following:

$$\Delta U = \sum_{\ell=1}^d \partial_{X_\ell}^2 U + \partial_Y^2 U \quad \text{and} \quad \Delta_x U = \sum_{\ell=1}^d \partial_{x_\ell}^2 U.$$

Notice that the divergence with respect to the variable x is also defined for a function $U : \mathbb{R}^{d+1} \rightarrow \mathbb{R}^{d+1}$ by

$$\operatorname{div}_x U = \sum_{\ell=1}^d \partial_{x_\ell} U^{(\ell)}.$$

The normal derivative of a function U defined on Γ is defined by

$$\partial_N U = (N \cdot \nabla)U = - \sum_{\ell=1}^d \partial_{x_\ell} H \partial_{x_\ell} U - \partial_Y U.$$

3.2. Elementary problems. Let us define the problem at the main scale: it consists in considering the viscoelastic problem on the smooth domain, i.e. by truncating the rough boundary from the initial domain, associated to homogeneous conditions on both boundaries.

■ **Main order:**

$$\text{pb}^{(0)} \left\{ \begin{array}{ll} \operatorname{Re}(u_0 \cdot \nabla u_0) - (1-r)\Delta u_0 + \nabla p_0 - \operatorname{div}(\sigma_0) = f_0 + a_0, & \text{on } \omega_0 \\ \operatorname{div}(u_0) = 0, & \text{on } \omega_0 \\ \operatorname{We}(u_0 \cdot \nabla \sigma_0 + g_a(\nabla u_0, \sigma_0)) + \sigma_0 - D\Delta \sigma_0 = 2r\mathbb{D}(u_0), & \text{on } \omega_0 \\ u_0 = 0, & \text{on } \gamma_0^- \cup \gamma^+ \\ \partial_n \sigma_0 = 0, & \text{on } \gamma^+ \\ \partial_n \sigma_0 = b_0, & \text{on } \gamma_0^- \end{array} \right.$$

where $f_0 = f$ is the source term coming from the modelisation, and where the constants a_0 and b_0 have to be fixed.

Remark 1. *The choice of constants a_0 and b_0 will be discussed further. Roughly speaking, they play the role of a degree of freedom which will be fixed in order to ensure the well-posedness of elementary problems and a suitable behavior of elementary solutions to be defined. From a practical point of view, we will set $a_0 = b_0 = 0$.*

Imposing the homogeneous Dirichlet condition on the smooth lower boundary γ_0^- instead of the oscillating one γ_ε^- is a source of error. Indeed, (u_0, p_0, σ_0) satisfies all the equations except the boundary condition at the oscillating boundary γ_ε^- . The value at the oscillating boundary can be determined by a Taylor expansion:

$$u_0(x, -\varepsilon H(\frac{x}{\varepsilon})) = \sum_{k=0}^{+\infty} \frac{(-\varepsilon H(\frac{x}{\varepsilon}))^k}{k!} \partial_y^k u_0(x, 0).$$

Since $u_0(x, 0) = 0$, one can check that $u_0|_{\gamma_\varepsilon^-}$ is of order ε , namely

$$u_0(x, -\varepsilon H(\frac{x}{\varepsilon})) = -\varepsilon H(\frac{x}{\varepsilon}) \partial_y u_0(x, 0) + \mathcal{O}(\varepsilon^2),$$

and this leading term of order ε will be counterbalanced by first the boundary layer corrector.

Remark 2. *Note that the other terms (of orders ε^2 , ε^3 etc.) will be treated and counterbalanced in subsequent boundary layer problems.*

Remark 3. *The same methodology applies for the Neumann condition related to the elastic tensor.*

As a consequence of the previous remarks, we define the following boundary layer problem.

■ **Correction with boundary layer n° 1:**

$$\text{PB}^{(1)} \left\{ \begin{array}{ll} -(1-r)\Delta U_1 + \nabla P_1 = 0, & \text{on } \Omega \\ \operatorname{div}(U_1) = 0, & \text{on } \Omega \\ U_1 = H\partial_y u_0|_{\gamma_\varepsilon^-}, & \text{on } \Gamma \\ -D\Delta\Sigma_1 = 0, & \text{on } \Omega \\ \partial_N \Sigma_1 = (\nabla H \cdot \nabla_x)\sigma_0|_{\gamma_\varepsilon^-} - b_0 & \text{on } \Gamma. \end{array} \right.$$

Remark 4. *Let us present the behavior of the solution (the proofs will be given by proposition 1 later).*

- (1) *When $Y \rightarrow +\infty$, the velocity U_1 exponentially decreases towards the constant defined as*

$$U_\infty := \lim_{Y \rightarrow \infty} \int_{\mathbb{T}^d} U_1(\cdot, Y).$$

- (2) *For $b_0 = 0$, the elastic tensor Σ_1 exponentially decreases towards 0.*

At this stage, it can be shown that the approximation satisfies the equations in the domain and at the oscillating boundary. At the upper boundary, the Neumann boundary condition for the elastic tensor is satisfied because of the exponential decay of σ_0 at infinity. However the homogeneous Dirichlet condition is not satisfied for the velocity field. This is why a so-called main corrector defined on the smooth domain is defined in order to counterbalance the boundary default introduced by the approximation at the upper boundary.

Defining the linear operators $\mathcal{L}^{(A)}$, $\mathcal{L}^{(B)}$ and $\mathcal{L}^{(C)}$ by

$$\begin{aligned} \mathcal{L}^{(A)}(u_1) &:= \operatorname{Re}(u_1 \cdot \nabla u_0 + u_0 \cdot \nabla u_1), \\ \mathcal{L}^{(B)}(u_1) &:= \operatorname{We}(u_1 \cdot \nabla \sigma_0 + g_a(\nabla u_1, \sigma_0)), \\ \mathcal{L}^{(C)}(\sigma_1) &:= \operatorname{We}(u_0 \cdot \nabla \sigma_1 + g_a(\nabla u_0, \sigma_1)), \end{aligned}$$

we define the following problems:

■ **Main correction n° 1:**

$$\text{pb}^{(1)} \left\{ \begin{array}{ll} \mathcal{L}^{(A)}(u_1) - (1-r)\Delta u_1 + \nabla p_1 = \operatorname{div}(\sigma_1) + a_1, & \text{on } \omega_0 \\ \operatorname{div}(u_1) = 0, & \text{on } \omega_0 \\ \mathcal{L}^{(B)}(u_1) + \mathcal{L}^{(C)}(\sigma_1) + \sigma_1 - D\Delta\sigma_1 = 2r\mathbb{D}(u_1), & \text{on } \omega_0 \\ u_1 = -\lim_{Y \rightarrow \infty} \int_{\mathbb{T}} U_1, & \text{on } \gamma^+ \\ u_1 = 0, & \text{on } \gamma_0^- \\ \partial_n \sigma_1 = 0, & \text{on } \gamma^+ \\ \partial_n \sigma_1 = b_1, & \text{on } \gamma_0^-. \end{array} \right.$$

■ **Correction with boundary layer n° 2:**

$$\text{PB}^{(2)} \left\{ \begin{array}{ll} -(1-r)\Delta U_2 + \nabla P_2 = F_2 - a_0, & \text{on } \Omega \\ \operatorname{div}(U_2) = 0, & \text{on } \Omega \\ U_2 = H\partial_y u_1|_{\gamma_0^-} - \frac{1}{2}H^2\partial_y^2 u_0|_{\gamma_0^-} & \text{on } \Gamma \\ -D\Delta\Sigma_2 = G_2, & \text{on } \Omega \\ \partial_N\Sigma_2 = -H\partial_y^2\sigma_0|_{\gamma_0^-} + (\nabla H \cdot \nabla_x)\sigma_1|_{\gamma_0^-} \\ \quad - H(\nabla H \cdot \nabla_x)\partial_y\sigma_0|_{\gamma_0^-} \\ \quad + (\nabla H \cdot \nabla_x)\Sigma_1 - b_1 & \text{on } \Gamma. \end{array} \right.$$

with

$$\begin{aligned} F_2 &:= \operatorname{div}(\Sigma_1) - \nabla_x P_1 + 2(1-r)\nabla_x \cdot \nabla U_1 - \operatorname{Re}(u_0 \cdot \nabla U_1), \\ G_2 &:= 2r\mathbb{D}(U_1) + 2D\nabla_x \cdot \nabla\Sigma_1 - \operatorname{We}(u_0 \cdot \nabla\Sigma_1 + g_a(\nabla U_1, \sigma_0)). \end{aligned}$$

Remark 5. *With a suitable choice of a_0 (resp. b_1), the problem related to the velocity field (resp. constraint field) is well-posed and satisfies the property with exponential decay towards a constant (resp. 0). Moreover, b_1 does not depend on σ_1 !*

■ **Main correction at order $k \geq 2$:**

$$\text{pb}^{(k)} \left\{ \begin{array}{ll} \mathcal{L}^{(A)}(u_k) - (1-r)\Delta u_k + \nabla p_k = \operatorname{div}(\sigma_k) + f_k + a_k & \text{on } \omega_0, \\ \operatorname{div}(u_k) = 0 & \text{on } \omega_0, \\ \mathcal{L}^{(B)}(u_k) + \mathcal{L}^{(C)}(\sigma_k) + \sigma_k - D\Delta\sigma_k = 2r\mathbb{D}(u_k) + g_k & \text{on } \omega_0, \\ u_k = -\lim_{Y \rightarrow \infty} \int_{\mathbb{T}} U_k & \text{on } \gamma^+, \\ u_k = 0 & \text{on } \gamma_0^-, \\ \partial_n \sigma_k = 0 & \text{on } \gamma^+, \\ \partial_n \sigma_k = b_k & \text{on } \gamma_0^-. \end{array} \right.$$

where f_k and g_k only depend on solutions that were defined previously:

$$\begin{aligned} f_k &:= -\operatorname{Re} \sum_{i=1}^{k-1} u_i \cdot \nabla u_{k-i}, \\ g_k &:= \operatorname{We} \sum_{i=1}^{k-1} (u_i \cdot \nabla \sigma_{k-i} + g(\nabla u_i, \sigma_{k-i})). \end{aligned}$$

Higher order correction terms of the asymptotic expansion are defined as the solutions of the following elementary problems.

■ **Correction with boundary layer of order $k \geq 3$:**

$$\text{PB}^{(k)} \left\{ \begin{array}{ll} -(1-r)\Delta U_k + \nabla P_k = F_k - a_{k-2} & \text{on } \Omega, \\ \operatorname{div}(U_k) = 0 & \text{on } \Omega, \\ U_k = D_k & \text{on } \Gamma, \\ -D\Delta\Sigma_k = G_k & \text{on } \Omega, \\ \partial_N\Sigma_k = N_k - b_{k-1} & \text{on } \Gamma, \end{array} \right.$$

where F_k , D_k , G_k and N_k only depend on solutions that were defined previously.

$$\begin{aligned}
 F_k &:= \operatorname{div}(\Sigma_{k-1}) + 2(1-r)\nabla_x \cdot \nabla U_{k-1} \\
 &\quad + (1-r)\Delta_x U_{k-2} - \nabla_x P_{k-1} + \operatorname{div}_x(\Sigma_{k-2}) \\
 &\quad - \operatorname{Re} \sum_{i=0}^{k-2} ((u_i + U_i) \cdot (\nabla U_{k-1-i} + \nabla_x U_{k-2-i}) + U_i \cdot \nabla u_{k-i-2}), \\
 D_k &:= - \sum_{p=1}^k \frac{(-1)^p}{p!} H^p \partial_y^{(p)} u_{k-p}|_b, \\
 G_k &:= 2r\mathbb{D}(U_{k-1}) + 2r\mathbb{D}_x(U_{k-2}) - \Sigma_{k-2} + 2\mathbb{D} \nabla_x \cdot \nabla \Sigma_{k-1} + \mathbb{D} \Delta_x \Sigma_{k-2} \\
 &\quad - \operatorname{We} \left(\sum_{i=0}^{k-2} u_i \cdot (\nabla \Sigma_{k-1-i} + \nabla_x \Sigma_{k-i-2}) \right. \\
 &\quad \left. + U_i \cdot (\nabla \sigma_{k-i-2} + \nabla \Sigma_{k-1-i} + \nabla_x \Sigma_{k-i-2}) \right. \\
 &\quad \left. + g_a(\nabla u_i, \Sigma_{k-i-2}) + g_a(\nabla U_{i+1} + \nabla_x U_i, \sigma_{k-i-2} + \Sigma_{k-i-2}) \right), \\
 N_k &:= (\nabla H \cdot \nabla_x) \sigma_{k-1}|_{\gamma_0^-} + (\nabla H \cdot \nabla_x) \Sigma_{k-1} \\
 &\quad + \sum_{p=1}^{k-1} \frac{(-1)^p}{p!} H^p \partial_y^{(p)} ((\nabla H \cdot \nabla_x) \sigma_{k-1-p} + \partial_y \sigma_{k-1-p})|_{\gamma_0^-}.
 \end{aligned}$$

4. ANALYSIS OF THE ELEMENTARY PROBLEMS: WELL-POSEDNESS AND PROPERTIES OF THE SOLUTIONS

The elementary problems related to the boundary layer correctors with respect to the velocity take the following form:

$$\text{PB}^{(\text{ref1})} \begin{cases} -(1-r)\Delta U + \nabla P = F & \text{on } \Omega, \\ \operatorname{div}(U) = 0 & \text{on } \Omega, \\ U = D & \text{on } \Gamma, \end{cases}$$

with $F \in L^2(\Omega)$ and $D \in L^2(\mathbb{T}^d)$.

Notation 3. We denote \widehat{F}_j the following Fourier coefficients of a function F defined on $\mathbb{T}^d \times (0, +\infty)$:

$$F(X, Y) = \sum_{j \in \mathbb{Z}^d} \widehat{F}_j(Y) e^{2\pi i j \cdot X}.$$

Notation 4. All constants depending only on the domain and on physical constants will be considered harmless, there will be denoted C . In the same way, we will use the notation $Q(Y)$ to denote any polynomial with coefficients depending only on the domain or on physical constant. In particular the quantities C and $Q(Y)$ do not depend on the variables x or X .

Proposition 1. If the following conditions are satisfied

$$\begin{aligned}
 \left\| \widehat{F}_0(Y) \right\| &\leq Q(Y) e^{-Y}, & \text{for all } Y > 0, \\
 \left\| \widehat{F}_j(Y) \right\| &\leq Q(Y) e^{-\|j\|Y}, & \text{for all } j \in \mathbb{Z}^d \setminus \{0\} \text{ and } Y > 0,
 \end{aligned}$$

then $\text{PB}^{(\text{ref1})}$ admits a unique solution (U, P) satisfying $\nabla U \in L^2(\Omega)$ and $P \in L^2(\Omega)$.

(1) There exists $U_\infty \in \mathbb{R}^d$ such that

$$\begin{aligned} \left\| \widehat{U}_0(Y) - U_\infty \right\| + \left| \widehat{P}_0(Y) \right| &\leq Q(Y) e^{-Y}, & \text{for all } Y > 0, \\ \left\| \widehat{U}'_0(Y) \right\| + \left| \widehat{P}'_0(Y) \right| &\leq Q(Y) e^{-Y}, & \text{for all } Y > 0. \end{aligned}$$

(2) We have

$$\begin{aligned} \|U(X, Y) - U_\infty\| + |P(X, Y)| &\leq Q(Y) e^{-Y}, & \text{for all } X \in \mathbb{T}^d, Y > 0, \\ \text{and, for all } \ell \geq 1, \\ \|\partial_X^\ell U(X, Y)\| + |\partial_X^\ell P(X, Y)| &\leq Q(Y) e^{-Y}, & \text{for all } X \in \mathbb{T}^d, Y > 0. \end{aligned}$$

Remark 6. In this Proposition, the vector U_∞ can be identified as the limit of $\widehat{U}_0(Y)$ when Y goes to $+\infty$:

$$U_\infty := \lim_{Y \rightarrow \infty} \int_{\mathbb{T}} U \in \mathbb{R}^d.$$

Proof. Let us introduce the following decomposition of the vectors $U = (U^{(1)}, U^{(2)}) \in \mathbb{R}^d \times \mathbb{R}$ and $F = (F^{(1)}, F^{(2)}) \in \mathbb{R}^d \times \mathbb{R}$. Then, we pass to the Fourier transform with respect to X . Passing in the Fourier regime, equations satisfied by (U, P) inside the domain Ω , in problem PB⁽¹⁾, can be translated into

$$(5) \quad \begin{cases} \|j\|^2 \widehat{U}_j^{(1)} - \widehat{U}_j^{(1)''} + ij \widehat{P}_j = \widehat{F}_j^{(1)} & \text{on } \{Y > 0\} & \forall j \in \mathbb{Z}^d, \\ \|j\|^2 \widehat{U}_j^{(2)} - \widehat{U}_j^{(2)''} + \widehat{P}_j' = \widehat{F}_j^{(2)} & \text{on } \{Y > 0\} & \forall j \in \mathbb{Z}^d, \\ ij \cdot \widehat{U}_j^{(1)} + \widehat{U}_j^{(2)'} = 0 & \text{on } \{Y > 0\} & \forall j \in \mathbb{Z}^d, \end{cases}$$

where $\widehat{U}_j^{(1)'}$, $\widehat{U}_j^{(2)'}$ and \widehat{P}_j belong to $L^2(0, +\infty)$. Now we solve the Fourier problem and describe the behavior of the solution of the Stokes problem.

(1) Let us discuss the case $j = 0$. The system reduces to

$$\begin{cases} -\widehat{U}_0^{(1)''} = \widehat{F}_0^{(1)} & \text{with } \widehat{U}_0^{(1)'} \in L^2(0, +\infty), \\ -\widehat{U}_0^{(2)''} + \widehat{P}_0' = \widehat{F}_0^{(2)} & \text{with } \widehat{P}_0 \in L^2(0, +\infty), \\ \widehat{U}_0^{(2)'} = 0 & \text{with } \widehat{U}_0^{(2)'} \in L^2(0, +\infty). \end{cases}$$

By integration, this leads us to the following equalities

$$\begin{aligned} \widehat{U}_0^{(1)'}(Y) &= \int_Y^{+\infty} \widehat{F}_0^{(1)}(\xi) d\xi, \\ \widehat{U}_0^{(2)'}(Y) &= 0, \\ \widehat{U}_0^{(1)}(Y) &= \widehat{U}_0^{(1)}(0) - \int_0^{+\infty} \left(\int_Z^{+\infty} \widehat{F}_0^{(1)}(\xi) d\xi \right) dZ \\ &\quad + \int_Y^{+\infty} \left(\int_Z^{+\infty} \widehat{F}_0^{(1)}(\xi) d\xi \right) dZ, \\ \widehat{U}_0^{(2)}(Y) &= \widehat{U}_0^{(2)}(0), \\ \widehat{P}_0(Y) &= - \int_Y^{+\infty} \widehat{F}_0^{(2)}(Z) dZ. \end{aligned}$$

By assumption on the source term, we have

$$\begin{aligned} \left| \int_Y^{+\infty} \int_Z^{+\infty} \widehat{F}_0^{(1)}(\zeta) \, d\zeta \, dZ \right| &\leq Q(Y) e^{-Y} \\ \left| \int_Y^{+\infty} \widehat{F}_0^{(\ell)}(Z) \, dZ \right| &\leq Q(Y) e^{-Y}, \quad \ell = 1, 2. \end{aligned}$$

Defining $U_\infty := (U_\infty^{(1)}, U_\infty^{(2)}) \in \mathbb{R}^d \times \mathbb{R}$ as

$$\begin{aligned} U_\infty^{(1)} &:= \widehat{U}_0^{(1)}(0) - \int_0^{+\infty} \left(\int_Z^{+\infty} \widehat{F}_0^{(1)}(\xi) \, d\xi \right) \, dZ, \\ U_\infty^{(2)} &:= \widehat{U}_0^{(2)}(0), \end{aligned}$$

we obtain, for all $Y > 0$,

$$\begin{aligned} |\widehat{U}_0^{(1)}(Y) - U_\infty^{(1)}| + |\widehat{U}_0^{(2)}(Y) - U_\infty^{(2)}| + |\widehat{P}_0(Y)| &\leq Q(Y) e^{-Y}, \\ |\widehat{U}_0^{(1)'}(Y)| + |\widehat{U}_0^{(2)'}(Y)| + |\widehat{P}_0'(Y)| &\leq Q(Y) e^{-Y}. \end{aligned}$$

- (2) Let us discuss the case $j \neq 0$. If the source terms $\widehat{F}_j^{(1)}$ and $\widehat{F}_j^{(2)}$ were written as $Q(Y)e^{-\|j\|Y}$ then the estimate is proved in [15, Appendix B]. In the present case, the source terms only satisfy

$$\begin{aligned} \|\widehat{F}_j^{(1)}(Y)\| &\leq Q(Y) e^{-\|j\|Y}, \quad \forall Y > 0, \\ |\widehat{F}_j^{(2)}(Y)| &\leq Q(Y) e^{-\|j\|Y}, \quad \forall Y > 0, \end{aligned}$$

and the proof can be adapted from [15] by using a comparison principle. In particular, we can show that

$$\left\| \widehat{U}_j(Y) \right\| + \left| \widehat{P}_j(Y) \right| \leq Q(Y) e^{-\|j\|Y}, \quad \text{for all } j \in \mathbb{Z}^d \setminus \{0\} \text{ and } Y > 0.$$

□

The elementary problems related to the boundary layer correctors with respect to the elastic constraint take the following form:

$$\text{PB}^{(\text{ref2})} \begin{cases} -\Delta \Sigma = G & \text{on } \Omega, \\ \partial_N \Sigma = N & \text{on } \Gamma, \end{cases}$$

with $G \in L^2(\Omega)$ and $N \in L^2(\mathbb{T}^d)$.

We note that the problems related to the boundary layer correctors are matricial problems: the unknowns Σ_k have matricial values. The elementary problem that we analyze here is a scalar case but can easily be extended component by component.

Proposition 2. *Assume that*

$$\int_{\{Y < 0\}} G(X, Y) \, dX \, dY = \int_{\mathbb{T}^d} N(X) \, dX.$$

If the following conditions are satisfied

$$\begin{aligned} \left| \widehat{G}_0(Y) \right| &\leq Q(Y) e^{-Y}, \quad \text{for all } Y > 0, \\ \left| \widehat{G}_j(Y) \right| &\leq Q(Y) e^{-\|j\|Y}, \quad \text{for all } j \in \mathbb{Z}^d \setminus \{0\} \text{ and } Y > 0, \end{aligned}$$

then $\text{PB}^{(\text{ref}2)}$ admits a unique solution $\Sigma \in L^2(\Omega)$. Moreover, we have

$$\begin{aligned} |\widehat{\Sigma}_0(Y)| &\leq Q(Y) e^{-Y}, & \text{for all } Y > 0, \\ |\widehat{\Sigma}_j(Y)| &\leq Q(Y) e^{-\|j\|Y}, & \text{for all } j \in \mathbb{Z}^d \setminus \{0\} \text{ and } Y > 0. \end{aligned}$$

In particular, we have

$$|\Sigma(X, Y)| \leq Q(Y) e^{-Y}, \quad \text{for all } X \in \mathbb{T}^d, Y > 0.$$

Proof. If the source terms satisfy $\widehat{G}_0 = 0$ and, for $j \geq 1$, $\widehat{G}_j(Y) = Q(Y) e^{-\|j\|Y}$, then the estimate is proved in [14, Lemma 2.2]. In the present case, the source terms only satisfy

$$|\widehat{G}_0(Y)| \leq Q(Y) e^{-Y} \quad \text{and} \quad |\widehat{G}_j(Y)| \leq Q(Y) e^{-\|j\|Y}.$$

The estimate on $\widehat{\Sigma}_0$ can be obtained by straightforward integration. For $j \neq 0$, the proof can be adapted from [14] by using a comparison principle. \square

Applications: analysis of problems $\text{PB}^{(k)}$. Let us recall that the definition of the boundary layer correction problems $\text{PB}^{(k)}$ need to specify the value of a_{k-2} and b_{k-1} . Let us first describe how to determine a_{k-2} . In order to apply Proposition 1, we need to impose that the source term in the momentum equation of $\text{PB}^{(k)}$, namely $F := F_k - a_{k-2}$, satisfies a sharp decrease for each Fourier mode:

- Averaging this source term F with respect to X gives

$$\begin{aligned} \widehat{F}_0(Y) &= \int_{\mathbb{T}^d} (F_k(X, Y) - a_{k-2}) \, dX \\ &= \left(\int_{\mathbb{T}^d} F_k(X, Y) \, dX - \lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} F_k(X, Y) \, dX \right) \\ &\quad + \left(\lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} F_k(X, Y) \, dX - a_{k-2} \right). \end{aligned}$$

On one hand, F_k is composed of elementary solutions $(U_i, \widetilde{\Sigma}_i, P_i)_{1 \leq i \leq k-1}$ which, by induction, satisfy the expected decreasing behavior. We have

$$\left| \int_{\mathbb{T}^d} F_k(X, Y) - \lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} F_k(X, Y) \, dX \right| \leq Q(Y) e^{-Y}.$$

On the other hand, in order to satisfy the assumption needed to apply Proposition 1, we impose

$$(6) \quad a_{k-2} = \lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} F_k(X, Y) \, dX.$$

- By induction on k , the Fourier coefficients \widehat{F}_j , for $j \neq 0$, of the source term $F = F_k - a_{k-2}$ satisfy

$$\left\| \widehat{F}_j(Y) \right\| \leq Q(Y) e^{-\|j\|Y}, \quad \forall j \in \mathbb{Z}^d \setminus \{0\}, \quad \forall Y > 0.$$

Let us now describe how to determine b_{k-1} . In order to apply Proposition 2, we need to impose the compatibility condition between the source term in the Laplace

equation of $\text{PB}^{(k)}$, namely $G := \text{D}^{-1}G_k$, and the Neumann boundary term $N = N_k - b_{k-1}$:

$$(7) \quad b_{k-1} = \int_{\mathbb{T}^d} N_k(X) \, dX - \text{D}^{-1} \int_{Y < 0} G_k(X, Y) \, dX \, dY.$$

Besides, by induction on k , the Fourier coefficients \widehat{G}_j of the source term $G := \text{D}^{-1}G_k$ satisfy

$$\begin{aligned} \|\widehat{G}_0(Y)\| &\leq Q(Y) e^{-Y}, \quad \forall Y > 0, \\ \|\widehat{G}_j(Y)\| &\leq Q(Y) e^{-\|j\|Y}, \quad \forall j \in \mathbb{Z}^d \setminus \{0\}, \quad \forall Y > 0. \end{aligned}$$

5. ERROR ESTIMATES

5.1. Remainder. The asymptotic expansion truncated at a given order leads us to introduce the so-called remainder $(\mathcal{R}, \mathcal{Q}, \mathcal{S})$:

$$\begin{aligned} u(x) &= \sum_{j=0}^N \varepsilon^j \left[u_j(x) + U_j\left(x, \frac{x}{\varepsilon}\right) \right] + \varepsilon^N \mathcal{R}(x), \\ p(x) &= \sum_{j=0}^N \varepsilon^j \left[p_j(x) + P_{j+1}\left(x, \frac{x}{\varepsilon}\right) \right] + \varepsilon^N \mathcal{Q}(x), \\ \sigma(x) &= \sum_{j=0}^N \varepsilon^j \left[\sigma_j(x) + \Sigma_j\left(x, \frac{x}{\varepsilon}\right) \right] + \varepsilon^N \mathcal{S}(x). \end{aligned}$$

We aim at establishing estimates on the remainder, *at any order*.

Applying the Oldroyd operator to the remainder $(\mathcal{R}, \mathcal{Q}, \mathcal{S})$ and considering the properties of the elementary solutions, we get the following set of equations

- momentum equation, in ω_ε :

$$\text{Re} \left(\varepsilon^N \mathcal{R} \cdot \nabla \mathcal{R} + \mathcal{L}_\varepsilon^{(A)}(\mathcal{R}) \right) - (1-r)\Delta \mathcal{R} + \nabla \mathcal{Q} = \text{div}(\mathcal{S}) + \mathcal{F}_\varepsilon,$$

- continuity equation, in ω_ε :

$$\text{div}(\mathcal{R}) = 0,$$

- constitutive equation, in ω_ε :

$$\begin{aligned} \text{We} \left(\varepsilon^N (\mathcal{R} \cdot \nabla \mathcal{S} + g_a(\nabla \mathcal{R}, \mathcal{S})) + \mathcal{L}_\varepsilon^{(B)}(\mathcal{R}) + \mathcal{L}_\varepsilon^{(C)}(\mathcal{S}) \right) + \mathcal{S} - \text{D}\Delta \mathcal{S} \\ = 2r\mathbb{D}(\mathcal{R}) + \mathcal{G}_\varepsilon, \end{aligned}$$

- boundary conditions on the velocity, on $\gamma_\varepsilon^- \cup \gamma_\varepsilon^+$:

$$\mathcal{R} = \mathcal{D}_\varepsilon^{(\pm)},$$

- boundary conditions on the elastic constraint, on $\gamma_\varepsilon^- \cup \gamma_\varepsilon^+$:

$$\partial_{\mathbf{n}} \mathcal{S} = \mathcal{N}_\varepsilon^{(\pm)},$$

where operators are defined as follows.

$$\begin{aligned}
\mathcal{L}_\varepsilon^{(A)}(\mathcal{R}) &= \mathcal{R} \cdot \left(\sum_{k=0}^{N-1} \varepsilon^k (\nabla u_k + \nabla_x U_k + \nabla U_{k+1}) \right) \\
&\quad + \varepsilon^N \mathcal{R} \cdot (\nabla u_N + \nabla_x U_N) + \left(\sum_{k=0}^N \varepsilon^k (u_k + U_k) \right) \cdot \nabla \mathcal{R}, \\
\mathcal{L}_\varepsilon^{(B)}(\mathcal{R}) &= \mathcal{R} \cdot \left(\sum_{k=0}^{N-1} \varepsilon^k (\nabla \sigma_k + \nabla_x \Sigma_k + \nabla \Sigma_{k+1}) \right) \\
&\quad + \varepsilon^N \mathcal{R} \cdot (\nabla \sigma_N + \nabla_x \Sigma_N) + g_a \left(\nabla \mathcal{R}, \sum_{k=0}^N \varepsilon^k (\sigma_k + \Sigma_k) \right), \\
\mathcal{L}_\varepsilon^{(C)}(\mathcal{S}) &= \left(\sum_{k=0}^N \varepsilon^k (u_k + U_k) \right) \cdot \nabla \mathcal{S} + \varepsilon^N g_a (\nabla u_N + \nabla_x U_N, \mathcal{S}) \\
&\quad + g_a \left(\sum_{k=0}^{N-1} \varepsilon^k (\nabla u_k + \nabla_x U_k + \nabla U_{k+1}), \mathcal{S} \right).
\end{aligned}$$

The source terms are defined by

$$\begin{aligned}
\mathcal{F}_\varepsilon &= -\operatorname{Re} \left(\sum_{k=1}^N (u_k + U_k) \cdot (\nabla u_{N-k} + \nabla_x U_{N-k} + \nabla U_{N+1-k}) \right) \\
&\quad - \operatorname{Re} u_0 \cdot (\nabla u_N + \nabla_x U_N) + (1-r) \Delta_x U_N + (1-r) \Delta_x U_N \\
&\quad - \nabla p_N - \nabla_x P_{N+1} + \operatorname{div}(\sigma_N) + \operatorname{div}_x(\Sigma_N), \\
\mathcal{G}_\varepsilon &= 2r \mathbb{D}(u_N) + 2r \mathbb{D}_x(U_N) - \sigma_N - \Sigma_N + \mathbb{D} \Delta \sigma_N + \mathbb{D} \Delta_x \Sigma_N \\
&\quad - \operatorname{We} \sum_{k=1}^N \left((u_k + U_k) \cdot (\nabla \sigma_{N-k} + \nabla_x \Sigma_{N-k} + \nabla \Sigma_{N+1-k}) \right) \\
&\quad - \operatorname{We} u_0 \cdot (\nabla \sigma_N + \nabla_x \Sigma_N) \\
&\quad - \operatorname{We} \sum_{k=0}^{N-1} \left(g_a (\nabla u_k + \nabla_x U_k + \nabla U_{k+1}, \sigma_{N-k} + \Sigma_{N-k}) \right) \\
&\quad - \operatorname{We} g_a (\nabla u_N + \nabla_x U_N, \sigma_0),
\end{aligned}$$

and the contributions to the boundary relation are given by

$$\begin{aligned}
\mathcal{D}_\varepsilon^{(+)} &= \sum_{k=0}^N \varepsilon^{k-N} \left(\lim_{Y \rightarrow \infty} \int_{\mathbb{T}} U_k - U_k|_{Y=1/\varepsilon} \right), \\
\mathcal{D}_\varepsilon^{(-)} &= -\varepsilon^{-N} \sum_{k=0}^N \varepsilon^k \sum_{i=N-k+1}^{+\infty} \frac{(-\varepsilon H)^i}{i!} \partial_y^{(i)} u_k|_{\gamma_0^-}, \\
\mathcal{N}_\varepsilon^{(+)} &= -\sum_{k=0}^{N-1} \varepsilon^{k-N} \partial_Y \Sigma_{k+1}|_{y=1, Y=1/\varepsilon}, \\
\mathcal{N}_\varepsilon^{(-)} &= -\varepsilon^{-N} \sum_{k=0}^N \varepsilon^k \sum_{i=N-k+1}^{+\infty} \frac{(-\varepsilon H)^i}{i!} \partial_y^{(i)} ((\nabla H \cdot \nabla_x) \sigma_k + \partial_y \sigma_k)|_{\gamma_0^-}.
\end{aligned}$$

Proposition 3. *The following estimates hold:*

$$\|\mathcal{F}_\varepsilon\|_{L^2} \leq C, \quad \|\mathcal{G}_\varepsilon\|_{L^2} \leq C.$$

For all $\ell \geq 0$, for all $x \in \mathbb{T}^d$, we have

$$\begin{aligned} |\nabla_x^\ell \mathcal{D}_\varepsilon^{(+)}(x)| &\leq Q \left(\frac{1}{\varepsilon} \right) e^{-\frac{1}{\varepsilon}}, & |\nabla_x^\ell \mathcal{D}_\varepsilon^{(-)}(x)| &\leq C \varepsilon^{1-\ell}, \\ |\nabla_x^\ell \mathcal{N}_\varepsilon^{(+)}(x)| &\leq Q \left(\frac{1}{\varepsilon} \right) e^{-\frac{1}{\varepsilon}}, & |\nabla_x^\ell \mathcal{N}_\varepsilon^{(-)}(x)| &\leq C \varepsilon^{1-\ell}. \end{aligned}$$

Proof.

- The estimates for \mathcal{F}_ε and \mathcal{G}_ε are obvious.
- By using Proposition 1, we know that for each integer k we have

$$\left\| U_k \left(x, \frac{x}{\varepsilon}, \frac{1}{\varepsilon} \right) - \lim_{Y \rightarrow \infty} \int_{\mathbb{T}} U_k \right\| \leq Q \left(\frac{1}{\varepsilon} \right) e^{-\frac{1}{\varepsilon}}, \quad \text{for all } x \in \mathbb{T}^d,$$

and, for all $\ell \geq 1$,

$$\left\| \nabla_X^\ell U_k \left(x, \frac{x}{\varepsilon}, \frac{1}{\varepsilon} \right) \right\| \leq Q \left(\frac{1}{\varepsilon} \right) e^{-\frac{1}{\varepsilon}}, \quad \text{for all } x \in \mathbb{T}^d.$$

We immediately deduce that for all $\ell \geq 0$ and for all $x \in \mathbb{T}^d$ we have

$$|\nabla_x^\ell \mathcal{D}_\varepsilon^{(+)}(x)| \leq Q \left(\frac{1}{\varepsilon} \right) e^{-\frac{1}{\varepsilon}}.$$

- We estimate $\nabla_x^\ell \mathcal{D}_\varepsilon^{(-)}$ remarking that, using the Taylor formulae, for each integer k we can write

$$\sum_{i=N-k+1}^{+\infty} \frac{(-\varepsilon H)^i}{i!} \partial_y^{(i)} u_k(x, 0) = \frac{(-\varepsilon H)^{N-k+1}}{(N-k+1)!} \partial_y^{(N-k+1)} u_k(x, \xi_k),$$

with $\xi_k \in [0, -\varepsilon H(x/\varepsilon)]$. That implies

$$\mathcal{D}_\varepsilon^{(-)}(x, -\varepsilon H(x/\varepsilon)) = -\varepsilon \sum_{k=0}^N \frac{(-H)^{N-k+1}}{(N-k+1)!} \partial_y^{(N-k+1)} u_k(x, \xi_k).$$

Now, since $\mathcal{D}_\varepsilon^{(-)}$ is a finite sum, the estimate directly follows from its analysis.

- Finally, the estimate on $\nabla_x^\ell \mathcal{N}_\varepsilon^{(\pm)}$ is based on the same arguments, noticing that the Neumann data, for the remainder, can be reduced to a *finite* sum of boundary terms, namely

$$\begin{aligned} &\mathcal{N}_\varepsilon^{(N)}(x, -\varepsilon H(x/\varepsilon)) \\ &= \varepsilon \sum_{k=0}^N \frac{(-H)^{N-k+1}}{(N-k+1)!} \partial_y^{(N-k+1)} ((\nabla H \cdot \nabla_x) \sigma_k + \partial_y \sigma_k)(x, \zeta_k). \end{aligned}$$

□

5.2. Lift procedure. Well-posedness of the set of equations satisfied by the remainder is obtained by means of construction. Let us point out the fact that the remainder satisfies a diffusive Oldroyd-type system.

In this step, we aim at modifying the set of equations by using a lift procedure in order to deal with *homogeneous* boundary conditions and preserve the *homogeneous* incompressibility condition.

Definition 3. Let $\tau \in C^\infty(\mathbb{R})$ be such that

$$\tau(y) = \begin{cases} 0 & \text{if } y \leq 0, \\ 1 & \text{if } y \geq 1. \end{cases}$$

We define $\mathcal{R}_{\text{bound}}$ and $\mathcal{S}_{\text{bound}}$ as

$$(8) \quad \begin{aligned} \mathcal{R}_{\text{bound}}(x, y) &= \tau(y) \mathcal{D}_\varepsilon^{(+)}(x) + (1 - \tau(y)) \mathcal{D}_\varepsilon^{(-)}(x), \\ \mathcal{S}_{\text{bound}}(x, y) &= \tau(y) \mathcal{N}_\varepsilon^{(+)}(x) + (1 - \tau(y)) \mathcal{N}_\varepsilon^{(-)}(x), \end{aligned}$$

and we define \mathcal{R}_{div} as a solution of

$$\begin{cases} \operatorname{div}(\mathcal{R}_{\text{div}}) = -\operatorname{div}(\mathcal{R}_{\text{bound}}) & \text{in } \omega_\varepsilon, \\ \mathcal{R}_{\text{div}} = 0 & \text{on } \gamma_\varepsilon^- \cup \gamma^+. \end{cases}$$

The lift velocity and constraint fields are thus defined as:

$$\mathcal{R}_{\text{lift}} := \mathcal{R}_{\text{bound}} + \mathcal{R}_{\text{div}}, \quad \mathcal{S}_{\text{lift}} := \mathcal{S}_{\text{bound}}$$

and the lifted velocity and constraint field are thus defined as:

$$\tilde{\mathcal{R}} := \mathcal{R} - \mathcal{R}_{\text{lift}}, \quad \tilde{\mathcal{Q}} := \mathcal{Q}, \quad \tilde{\mathcal{S}} := \mathcal{S} - \mathcal{S}_{\text{lift}}.$$

Remark 7. The lifted remainder $(\tilde{\mathcal{R}}, \tilde{\mathcal{S}})$ satisfies a system which is identical to the system satisfied by $(\mathcal{R}, \mathcal{S})$, up to some modifications:

- the boundary conditions are homogeneous ;
- the incompressibility condition is (still) homogeneous ;
- the source terms \mathcal{F}_ε , \mathcal{G}_ε , and linear operators $\mathcal{L}^{(A)}$, $\mathcal{L}^{(B)}$, $\mathcal{L}^{(C)}$ have been (slightly) modified (see further, page 19)

Remark 8. The definition of \mathcal{R}_{div} is guaranteed by the following result, due to Bogovskii [9] (see also [11]):

Proposition 4 (Bogovskii). If $\mathcal{H} \in H^m(\omega_\varepsilon)$, $m \geq 0$, is such that

$$\int_{\Omega_\varepsilon} \mathcal{H} = 0,$$

then there exists a solution $\tilde{\mathcal{R}} \in H^{m+1}(\omega_\varepsilon)$ of

$$\begin{cases} \operatorname{div}(\tilde{\mathcal{R}}) = \mathcal{H} & \text{in } \omega_\varepsilon, \\ \tilde{\mathcal{R}} = 0 & \text{on } \gamma_\varepsilon^- \cup \gamma^+, \end{cases}$$

such that

$$\|\nabla \tilde{\mathcal{R}}\|_{H^m(\omega_\varepsilon)} \leq C \|\mathcal{H}\|_{H^m(\omega_\varepsilon)}.$$

Thus, the existence of such a lift function $\tilde{\mathcal{R}}$ relies on the identity $\int_{\Omega_\varepsilon} \mathcal{H} = 0$ with $\mathcal{H} = -\operatorname{div}(\mathcal{R}_{\text{bound}})$. By the Stokes formula, we have

$$\int_{\Omega_\varepsilon} \operatorname{div}(\mathcal{R}_{\text{bound}}) = \int_{\gamma_\varepsilon^-} \mathcal{D}_\varepsilon^{(-)} \cdot \mathbf{n} + \int_{\gamma^+} \mathcal{D}_\varepsilon^{(+)} \cdot \mathbf{n} = \int_{\Omega_\varepsilon} \operatorname{div}(\mathcal{R}) = 0.$$

Proposition 5. The following estimates hold:

$$\|\mathcal{R}_{\text{lift}}\|_{H^2} \leq C \varepsilon^{-1}, \quad \|\mathcal{S}_{\text{lift}}\|_{H^2} \leq C \varepsilon^{-1}.$$

Proof.

- By definition of $\mathcal{R}_{\text{bound}}$ and $\mathcal{S}_{\text{bound}}$ (see 8), the estimates

$$\|\mathcal{R}_{\text{bound}}\|_{H^2} \leq C \varepsilon^{-1}, \quad \|\mathcal{S}_{\text{bound}}\|_{H^2} \leq C \varepsilon^{-1}.$$

directly follows from the Proposition 3.

- Following the Bogovskii inequality (see Proposition 4) and the Poincaré inequality, we have

$$\|\mathcal{R}_{\text{div}}\|_{H^2} \leq C \|\mathcal{R}_{\text{bound}}\|_{H^2}.$$

- Since $\mathcal{R}_{\text{lift}} = \mathcal{R}_{\text{bound}} + \mathcal{R}_{\text{div}}$ and $\mathcal{S}_{\text{lift}} = \mathcal{S}_{\text{bound}}$, the two previous steps imply the result of the Proposition 5. \square

Now estimates for a homogeneous (w.r.t. boundary conditions and incompressibility condition) system have to be established. This is the purpose of the next subsection.

5.3. Estimate on the remainder. The *lifted* remainder $(\tilde{\mathcal{R}}, \tilde{Q}, \tilde{\mathcal{S}})$ satisfies the following system:

- momentum equation, in ω_ε :

$$\varepsilon^N \operatorname{Re} \tilde{\mathcal{R}} \cdot \nabla \tilde{\mathcal{R}} + \widetilde{\mathcal{L}_\varepsilon^{(A)}}(\tilde{\mathcal{R}}) - (1-r)\Delta \tilde{\mathcal{R}} + \nabla \tilde{Q} = \operatorname{div}(\tilde{\mathcal{S}}) + \widetilde{\mathcal{F}_\varepsilon},$$

- constitutive equation, in ω_ε :

$$\begin{aligned} \varepsilon^N \operatorname{We} \left(\tilde{\mathcal{R}} \cdot \nabla \tilde{\mathcal{S}} + g_a(\nabla \tilde{\mathcal{R}}, \tilde{\mathcal{S}}) \right) + \widetilde{\mathcal{L}_\varepsilon^{(B)}}(\tilde{\mathcal{R}}) + \widetilde{\mathcal{L}_\varepsilon^{(C)}}(\tilde{\mathcal{S}}) + \tilde{\mathcal{S}} - \operatorname{D}\Delta \tilde{\mathcal{S}} \\ = 2r\mathbb{D}(\tilde{\mathcal{R}}) + \widetilde{\mathcal{G}_\varepsilon} \end{aligned}$$

- the *homogeneous* incompressibility condition, *homogeneous* Dirichlet conditions for the velocity, *homogeneous* Neumann conditions for the constraint.

The linear operators are given by:

$$\begin{aligned} \widetilde{\mathcal{L}_\varepsilon^{(A)}}(\tilde{\mathcal{R}}) &= \mathcal{L}_\varepsilon^{(A)}(\tilde{\mathcal{R}}) + \operatorname{Re} \varepsilon^N (\tilde{\mathcal{R}} \cdot \nabla \mathcal{R}_{\text{lift}} + \mathcal{R}_{\text{lift}} \cdot \nabla \tilde{\mathcal{R}}), \\ \widetilde{\mathcal{L}_\varepsilon^{(B)}}(\tilde{\mathcal{R}}) &= \mathcal{L}_\varepsilon^{(B)}(\tilde{\mathcal{R}}) + \operatorname{We} \varepsilon^N (\tilde{\mathcal{R}} \cdot \nabla \mathcal{S}_{\text{lift}} + g_a(\nabla \tilde{\mathcal{R}}, \mathcal{S}_{\text{lift}})), \\ \widetilde{\mathcal{L}_\varepsilon^{(C)}}(\tilde{\mathcal{S}}) &= \mathcal{L}_\varepsilon^{(C)}(\tilde{\mathcal{S}}) + \operatorname{We} \varepsilon^N (\mathcal{R}_{\text{lift}} \cdot \nabla \tilde{\mathcal{S}} + g_a(\nabla \mathcal{R}_{\text{lift}}, \tilde{\mathcal{S}})). \end{aligned}$$

The source terms are given by:

$$\begin{aligned} \widetilde{\mathcal{F}_\varepsilon} &= \mathcal{F}_\varepsilon - \operatorname{Re} \left(\varepsilon^N \mathcal{R}_{\text{lift}} \cdot \nabla \mathcal{R}_{\text{lift}} + \mathcal{L}_\varepsilon^{(A)}(\mathcal{R}_{\text{lift}}) \right) + (1-r)\Delta \mathcal{R}_{\text{lift}}, \\ \widetilde{\mathcal{G}_\varepsilon} &= \mathcal{G}_\varepsilon - \mathcal{S}_{\text{lift}} + \operatorname{D}\Delta \mathcal{S}_{\text{lift}} - \operatorname{We} (\mathcal{L}_\varepsilon^{(B)}(\mathcal{R}_{\text{lift}}) + \mathcal{L}_\varepsilon^{(C)}(\mathcal{S}_{\text{lift}})) \\ &\quad - \varepsilon^N \operatorname{We} (\mathcal{R}_{\text{lift}} \cdot \nabla \mathcal{S}_{\text{lift}} + g_a(\nabla \mathcal{R}_{\text{lift}}, \mathcal{S}_{\text{lift}})). \end{aligned}$$

Remark 9. From the Propositions 3 and 5 we can obtain a bound on the new source terms:

$$\|\widetilde{\mathcal{F}_\varepsilon}\|_{L^2} \leq C \varepsilon^{-1}, \quad \|\widetilde{\mathcal{G}_\varepsilon}\|_{L^2} \leq C \varepsilon^{-1}.$$

Theorem 2. The remainder satisfies:

$$\|\nabla \tilde{\mathcal{R}}\|_{L^2} + \|\tilde{\mathcal{S}}\|_{H^1} \leq C \varepsilon^{-1}.$$

Proof. Due to the relations between $(\mathcal{R}, \mathcal{S}, \mathcal{Q})$ and $(\tilde{\mathcal{R}}, \tilde{\mathcal{S}}, \tilde{\mathcal{Q}})$

$$\tilde{\mathcal{R}} := \mathcal{R} - \mathcal{R}_{\text{lift}}, \quad \tilde{\mathcal{Q}} := \mathcal{Q}, \quad \tilde{\mathcal{S}} := \mathcal{S} - \mathcal{S}_{\text{lift}},$$

using the Proposition 5, it suffices to analyze the error on $(\tilde{\mathcal{R}}, \tilde{\mathcal{S}}, \tilde{\mathcal{Q}})$.

The estimate is then obtained using a classical energy estimate on the system satisfied by $(\tilde{\mathcal{R}}, \tilde{\mathcal{S}}, \tilde{\mathcal{Q}})$. More precisely, we first take the scalar product in $L^2(\omega_\varepsilon)$ of the momentum equation by $2r\tilde{\mathcal{R}}$. Next we take the scalar product in $L^2(\omega_\varepsilon)$ of the constitutive equation by $\tilde{\mathcal{S}}$. We finally add the results to obtain

$$(9) \quad 2r(1-r) \int_{\omega} \|\nabla \tilde{\mathcal{R}}\|^2 + \int_{\omega} \|\tilde{\mathcal{S}}\|^2 + \text{D} \int_{\omega} \|\nabla \tilde{\mathcal{S}}\|^2 = \text{RHS}.$$

The term RHS is composed as follow:

$$\begin{aligned} \text{RHS} = & -2r \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(A)}(\tilde{\mathcal{R}}) \cdot \tilde{\mathcal{R}} + r \int_{\omega_\varepsilon} \widetilde{\mathcal{F}}_\varepsilon \cdot \tilde{\mathcal{R}} - \text{We} \varepsilon^N \int_{\omega} g_a(\nabla \tilde{\mathcal{R}}, \tilde{\mathcal{S}}) : \tilde{\mathcal{S}} \\ & - \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(B)}(\tilde{\mathcal{R}}) \cdot \tilde{\mathcal{S}} - \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(C)}(\tilde{\mathcal{S}}) \cdot \tilde{\mathcal{S}} + \int_{\omega_\varepsilon} \tilde{\mathcal{G}}_\varepsilon \cdot \tilde{\mathcal{S}}. \end{aligned}$$

It is not very difficult to show that the source terms and linear terms of RHS can be controlled by the terms on the left-hand side of the estimate (9). However the quadratic term does not lead in a straightforward way to a suitable estimate. Therefore we have to consider a new argument which is based on a fixed point procedure. Let us consider the following linearized system, denoted $(\mathbb{R}_{\text{lin}})$:

$$\begin{aligned} \varepsilon^N \text{Re} \tilde{\mathcal{R}}^n \cdot \nabla \tilde{\mathcal{R}}^{n+1} + \widetilde{\mathcal{L}}_\varepsilon^{(A)}(\tilde{\mathcal{R}}^{n+1}) - (1-r)\Delta \tilde{\mathcal{R}}^{n+1} + \nabla \tilde{\mathcal{Q}}^{n+1} \\ = \text{div}(\tilde{\mathcal{S}}^{n+1}) + \widetilde{\mathcal{F}}_\varepsilon, \end{aligned}$$

$$\begin{aligned} \varepsilon^N \text{We} \left(\tilde{\mathcal{R}}^n \cdot \nabla \tilde{\mathcal{S}}^{n+1} + g_a(\nabla \tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^{n+1}) \right) + \widetilde{\mathcal{L}}_\varepsilon^{(B)}(\tilde{\mathcal{R}}^{n+1}) + \widetilde{\mathcal{L}}_\varepsilon^{(C)}(\tilde{\mathcal{S}}^{n+1}) \\ + \tilde{\mathcal{S}}^{n+1} - \text{D}\Delta \tilde{\mathcal{S}}^{n+1} = 2r\mathbb{D}(\tilde{\mathcal{R}}^{n+1}) + \tilde{\mathcal{G}}_\varepsilon, \end{aligned}$$

and

$$\text{div} \tilde{\mathcal{R}}^{n+1} = 0.$$

where $(\tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^n)$ are given. The idea relies on the following arguments:

- (1) we show that $(\tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^n)_n$ is bounded in $H^1(\omega_\varepsilon)$, up to smallness assumptions ;
- (2) by the Cauchy criterion, we show that the sequence $(\tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^n)_n$ converges in $H^1(\omega_\varepsilon)$;
- (3) we let n tend to $+\infty$ and show that the limit of $(\tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^n)_n$ is the solution of the system satisfied by the remainder. The limit still satisfies the estimates of step 1.

Step 1. Using the classical energy estimate, we have

$$2r(1-r) \int_{\omega} \|\nabla \tilde{\mathcal{R}}^{n+1}\|^2 + \int_{\omega} \|\tilde{\mathcal{S}}^{n+1}\|^2 + \text{D} \int_{\omega} \|\nabla \tilde{\mathcal{S}}^{n+1}\|^2 = \text{RHS}^{(n)}.$$

The term $RHS^{(n)}$ is composed as follow:

$$\begin{aligned}
 RHS^{(n)} &= -2r \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(A)}(\widetilde{\mathcal{R}}^{n+1}) \cdot \widetilde{\mathcal{R}}^{n+1} + r \int_{\omega_\varepsilon} \widetilde{\mathcal{F}}_\varepsilon \cdot \widetilde{\mathcal{R}}^{n+1} \\
 &\quad - \text{We} \varepsilon^N \int_{\omega} g_a(\nabla \widetilde{\mathcal{R}}^n, \widetilde{\mathcal{S}}^{n+1}) : \widetilde{\mathcal{S}}^{n+1} \\
 &\quad - \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(B)}(\widetilde{\mathcal{R}}^{n+1}) \cdot \widetilde{\mathcal{S}}^{n+1} - \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(C)}(\widetilde{\mathcal{S}}^{n+1}) \cdot \widetilde{\mathcal{S}}^{n+1} \\
 &\quad + \int_{\omega_\varepsilon} \widetilde{\mathcal{G}}_\varepsilon \cdot \widetilde{\mathcal{S}}^{n+1}.
 \end{aligned}$$

We distinguish three types of terms:

- *source terms*

$$r \int_{\omega_\varepsilon} \widetilde{\mathcal{F}}_\varepsilon \cdot \widetilde{\mathcal{R}}^{n+1} + \int_{\omega_\varepsilon} \widetilde{\mathcal{G}}_\varepsilon \cdot \widetilde{\mathcal{S}}^{n+1}$$

Using Cauchy-Schwarz, Poincaré and Young inequalities, we have

$$\begin{aligned}
 \left| r \int_{\omega_\varepsilon} \widetilde{\mathcal{F}}_\varepsilon \cdot \widetilde{\mathcal{R}}^{n+1} \right| &\leq r \|\widetilde{\mathcal{F}}_\varepsilon\|_{L^2(\omega_\varepsilon)} \|\widetilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)} \\
 &\leq r C_P \|\widetilde{\mathcal{F}}_\varepsilon\|_{L^2(\omega_\varepsilon)} \|\nabla \widetilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)} \\
 &\leq r(1-r) \|\nabla \widetilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 + \frac{r}{4(1-r)} C_P^2 \|\widetilde{\mathcal{F}}_\varepsilon\|_{L^2(\omega_\varepsilon)}^2
 \end{aligned}$$

As a matter of fact, $r(1-r) \|\nabla \widetilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2$ can be absorbed by the left-hand side of the energy estimate. The other source term can be treated in a very similar way.

- *linear terms*

$$-2r \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(A)}(\widetilde{\mathcal{R}}^{n+1}) \cdot \widetilde{\mathcal{R}}^{n+1} - \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(B)}(\widetilde{\mathcal{R}}^{n+1}) \cdot \widetilde{\mathcal{S}}^{n+1} - \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(C)}(\widetilde{\mathcal{S}}^{n+1}) \cdot \widetilde{\mathcal{S}}^{n+1}.$$

Conventional arguments are the Hölder inequality, the Sobolev injections like $H^1(\omega_\varepsilon) \subset L^4(\omega_\varepsilon)$, with constant denoted C_S , and Young's inequality. For instance, the first term of $\widetilde{\mathcal{L}}_\varepsilon^{(A)}(\widetilde{\mathcal{R}}^{n+1})$, that is $\widetilde{\mathcal{R}}^{n+1} \cdot \nabla u_0$, can be treated as follows:

$$\begin{aligned}
 \left| 2r \int_{\omega_\varepsilon} (\widetilde{\mathcal{R}}^{n+1} \cdot \nabla u_0) \cdot \widetilde{\mathcal{R}}^{n+1} \right| &\leq 2r \|\widetilde{\mathcal{R}}^{n+1}\|_{L^4(\omega_\varepsilon)}^2 \|\nabla u_0\|_{L^2(\omega_\varepsilon)} \\
 &\leq 2r C_S \|\nabla \widetilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 \|\nabla u_0\|_{L^2(\omega_\varepsilon)}.
 \end{aligned}$$

Under smallness assumptions on u_0 (and therefore on the data of the initial problem), the right-hand side of the above inequality can be absorbed by the left-hand side of the energy estimate. The other linear terms can be treated in a very similar way.

- *quadratic terms*

$$-\text{We} \varepsilon^N \int_{\omega} g_a(\nabla \widetilde{\mathcal{R}}^n, \widetilde{\mathcal{S}}^{n+1}) : \widetilde{\mathcal{S}}^{n+1}.$$

Using the inequality

$$\begin{aligned} & \left| \text{We } \varepsilon^N \int_{\omega} g_a(\nabla \tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^{n+1}) : \tilde{\mathcal{S}}^{n+1} \right| \\ & \leq \text{We } \varepsilon^N \|\nabla \tilde{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)} \|\tilde{\mathcal{S}}^{n+1}\|_{L^4(\omega_\varepsilon)}^2 \\ & \leq \text{We } \varepsilon^N C_S \|\nabla \tilde{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)} \|\nabla \tilde{\mathcal{S}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 \end{aligned}$$

for ε sufficiently small (namely $\text{We } \varepsilon^N C_S \|\nabla \tilde{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)} < D$), then the right-hand side of the above inequality can be absorbed by the left-hand side of the energy estimate.

From the above considerations, we deduce the following estimate

$$\|\nabla \tilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 + \|\tilde{\mathcal{S}}^{n+1}\|_{H^1(\omega_\varepsilon)}^2 \leq C \|\tilde{\mathcal{F}}_\varepsilon\|_{L^2(\omega_\varepsilon)}^2 + C \|\tilde{\mathcal{G}}_\varepsilon\|_{L^2(\omega_\varepsilon)}^2.$$

By Remark 9, we obtain

$$(10) \quad \|\nabla \tilde{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 + \|\tilde{\mathcal{S}}^{n+1}\|_{H^1(\omega_\varepsilon)}^2 \leq C \varepsilon^{-2}.$$

Finally, in order to get the induction step on n , it is sufficient to guarantee that $\text{We } \varepsilon^{N-2} C_S C < D$ to get the uniform estimate on $(\tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^n)$. Note also that this condition is satisfied if ε is small enough.

Step 2. We prove that $(\tilde{\mathcal{R}}^n, \tilde{\mathcal{S}}^n)_n$ is a Cauchy sequence in $H^1(\omega_\varepsilon)$. Introducing

$$\hat{\mathcal{R}}^{n+1} := \tilde{\mathcal{R}}^{n+1} - \tilde{\mathcal{R}}^n, \quad \hat{\mathcal{S}}^{n+1} := \tilde{\mathcal{S}}^{n+1} - \tilde{\mathcal{S}}^n, \quad \hat{\mathcal{Q}}^{n+1} := \tilde{\mathcal{Q}}^{n+1} - \tilde{\mathcal{Q}}^n,$$

we get by subtraction in (R_{lin.})

$$\begin{aligned} & \varepsilon^N \text{Re} (\tilde{\mathcal{R}}^n \cdot \nabla \hat{\mathcal{R}}^{n+1} + \hat{\mathcal{R}}^n \cdot \nabla \tilde{\mathcal{R}}^n) + \widetilde{\mathcal{L}}_\varepsilon^{(A)}(\hat{\mathcal{R}}^{n+1}) - (1-r)\Delta \hat{\mathcal{R}}^{n+1} + \nabla \hat{\mathcal{Q}}^{n+1} \\ & \quad = \text{div}(\hat{\mathcal{S}}^{n+1}), \\ & \varepsilon^N \text{We} \left(\tilde{\mathcal{R}}^n \cdot \nabla \hat{\mathcal{S}}^{n+1} + \hat{\mathcal{R}}^n \cdot \nabla \tilde{\mathcal{S}}^n + g_a(\nabla \tilde{\mathcal{R}}^n, \hat{\mathcal{S}}^{n+1}) + g_a(\nabla \hat{\mathcal{R}}^n, \tilde{\mathcal{S}}^n) \right) \\ & \quad + \widetilde{\mathcal{L}}_\varepsilon^{(B)}(\hat{\mathcal{R}}^{n+1}) + \widetilde{\mathcal{L}}_\varepsilon^{(C)}(\hat{\mathcal{S}}^{n+1}) + \hat{\mathcal{S}}^{n+1} - D\Delta \hat{\mathcal{S}}^{n+1} = 2r\mathbb{D}(\hat{\mathcal{R}}^{n+1}) \end{aligned}$$

and

$$\text{div} \hat{\mathcal{R}}^{n+1} = 0.$$

Performing an energy estimate consists, again, in multiplying the first equation by $2r\hat{\mathcal{R}}^{n+1}$ then integrate over ω_ε , multiplying the second equation by $\hat{\mathcal{S}}^{n+1}$ then integrate over ω_ε and sum up the two contributions. We use the following estimates:

- The first contributions is easily controlled, as

$$\left| \varepsilon^N \text{Re} \int_{\omega_\varepsilon} (\tilde{\mathcal{R}}^n \cdot \nabla \hat{\mathcal{R}}^{n+1}) \cdot \hat{\mathcal{R}}^{n+1} \right| = 0.$$

- The second contribution satisfies:

$$\begin{aligned} & \left| \varepsilon^N \text{Re} \int_{\omega_\varepsilon} (\hat{\mathcal{R}}^n \cdot \nabla \tilde{\mathcal{R}}^n) \cdot \hat{\mathcal{R}}^{n+1} \right| \\ & \leq \varepsilon^N \text{Re} \|\hat{\mathcal{R}}^n\|_{L^4(\omega_\varepsilon)} \|\nabla \tilde{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)} \|\hat{\mathcal{R}}^{n+1}\|_{L^4(\omega_\varepsilon)} \\ & \leq C \varepsilon^{N-1} \|\nabla \hat{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)} \|\nabla \tilde{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)} \\ & \leq r(1-r) \|\nabla \hat{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 + \frac{C}{4r(1-r)} \varepsilon^{2N-2} \|\nabla \hat{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)}^2, \end{aligned}$$

where we have used the estimate established in Eq. (10) and then Sobolev imbedding and Young's inequality.

- The third contribution satisfies

$$\left| \int_{\omega_\varepsilon} \widetilde{\mathcal{L}}_\varepsilon^{(A)}(\widehat{\mathcal{R}}^{n+1}) \cdot \widehat{\mathcal{R}}^{n+1} \right| \leq \|\|\| \widetilde{\mathcal{L}}_\varepsilon^{(A)} \|\|\| \|\nabla \widehat{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2,$$

where $\|\|\| \cdot \|\|\|$ denotes the operator norm from $L^2(\omega_\varepsilon)$ to itself. Recalling the expression of $\widetilde{\mathcal{L}}_\varepsilon^{(A)}$, it can be shown that $\|\|\| \widetilde{\mathcal{L}}_\varepsilon^{(A)} \|\|\|$ is arbitrarily small for sufficiently small data or ε .

- The other contributions can be treated in a straightforward way or by arguments similar to the previous ones.

We thus deduce that, under smallness assumptions on the data and ε ,

$$\|\nabla \widehat{\mathcal{R}}^{n+1}\|_{L^2(\omega_\varepsilon)}^2 + \|\widehat{\mathcal{S}}^{n+1}\|_{H^1(\omega_\varepsilon)}^2 \leq C\varepsilon^{2N-2} (\|\nabla \widehat{\mathcal{R}}^n\|_{L^2(\omega_\varepsilon)}^2 + \|\widehat{\mathcal{S}}^n\|_{H^1(\omega_\varepsilon)}^2).$$

It means in particular that $(\widehat{\mathcal{R}}^{n+1} - \widehat{\mathcal{R}}^n, \widehat{\mathcal{S}}^{n+1} - \widehat{\mathcal{S}}^n)$ tends to 0 as n goes to $+\infty$. Consequently, $(\widehat{\mathcal{R}}^n, \widehat{\mathcal{S}}^n)$ is a Cauchy sequence in $H^1(\omega_\varepsilon)$. The sequence converges to some $(\widetilde{\mathcal{R}}^*, \widetilde{\mathcal{S}}^*)$ in $H^1(\omega_\varepsilon)$ which, by means of construction, satisfies the following estimate:

$$(11) \quad \|\nabla \widetilde{\mathcal{R}}^*\|_{L^2(\omega_\varepsilon)}^2 + \|\widetilde{\mathcal{S}}^*\|_{H^1(\omega_\varepsilon)}^2 \leq C\varepsilon^{-2}.$$

Step 3. Letting n tend to $+\infty$ we come to the conclusion that $(\widetilde{\mathcal{R}}^*, \widetilde{\mathcal{S}}^*)$ is the unique solution of the system satisfied by the lifted remainder. Therefore, the lifted remainder satisfies:

$$\|\nabla \widetilde{\mathcal{R}}\|_{L^2} + \|\widetilde{\mathcal{S}}\|_{H^1} \leq C\varepsilon^{-1}$$

which concludes the proof. \square

Corollary 3. *The asymptotic expansion is valid at any order.*

6. ALGORITHM AND NUMERICAL PROCEDURE

We show in this section that it is possible to effectively evaluate all the contributions of the ansatz. The only difficulty is to prove that the solution of each problem can be built using the only previous elementary solutions. For instance, let us prove that (u_k, p_k, σ_k) , which is the solution of the problem $pb^{(k)}$, only depends on (u_j, p_j, σ_j) , $j < k$ and on (U_j, P_j, Σ_j) , $j \leq k$. This is not so obvious since the problem $pb^{(k)}$ calls for the use of a parameter a_k , which seems to be related to a forthcoming problem $PB^{(k+2)}$ through the relationship

$$a_k = \lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} F_{k+2}(X, Y) \, dX.$$

However we know prove that the definition of a_k is a consistent:

Proposition 6. *Coefficients a_k (see the definition of $pb^{(k)}$ and $PB^{(k+2)}$) satisfying Eq. (6) can be written as*

$$a_k = \lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} \left[-\operatorname{Re} u_0 \cdot \nabla_x U_k + (1-r) \Delta_x U_k - \operatorname{Re} \sum_{i=1}^{k-1} u_i \cdot \nabla_x U_{k-i} - \operatorname{Re} \sum_{i=1}^k U_i \cdot (\nabla_x U_{k-i} + \nabla u_{k-i}) \right].$$

Proof. The source contribution F_{k+2} can be written as $F_{k+2}^A + F_{k+2}^B$ with

$$\begin{aligned} F_{k+2}^A &= \left[-\operatorname{Re} u_0 \cdot \nabla_x U_k + (1-r)\Delta_x U_k + \operatorname{div}_x(\Sigma_k) \right. \\ &\quad - \operatorname{Re} \sum_{i=1}^{k-1} u_i \cdot (\nabla U_{k+1-i} + \nabla_x U_{k-i}) \\ &\quad \left. - \operatorname{Re} \sum_{i=1}^k U_i \cdot (\nabla U_{k+1-i} + \nabla_x U_{k-i} + \nabla u_{k-i}) \right], \\ F_{k+2}^B &= -\operatorname{Re} u_0 \cdot \nabla U_{k+1} - \operatorname{Re} u_k \cdot \nabla U_1 + \operatorname{div}(\Sigma_{k+1}) \\ &\quad + 2(1-r)\nabla_x \cdot \nabla U_{k+1} - \nabla_x P_{k+1}. \end{aligned}$$

The first contribution F_{k+2}^A using the already defined elementary solutions $((u_j, p_j, \sigma_j)$, $j < k$ and (U_j, P_j, Σ_j) , $j \leq k$), whereas the second ones F_{k+2}^B using elementary solutions of problem $pb^{(k)}$ and $PB^{(k+1)}$.

We now prove that $\lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} F_{k+2}^B = 0$. For instance, we treat the first contribution (the four other contributions are similarly treated)

$$u_0 \cdot \nabla U_{k+1} = \sum_{\ell=1}^d u_0^{(\ell)} \partial_{X_\ell} U_{k+1} - u_0^{(d+1)} \partial_Y U_{k+1}.$$

Taking the X -average, using the periodicity we obtain

$$\int_{\mathbb{T}^d} u_0 \cdot \nabla U_{k+1} = u_0^{(d+1)} \partial_Y \left(\int_{\mathbb{T}^d} U_{k+1} \right).$$

Due to the behavior of the mean value $\int_{\mathbb{T}^d} U_{k+1}$ (see the Proposition 1), we have

$$\lim_{Y \rightarrow +\infty} \int_{\mathbb{T}^d} u_0 \cdot \nabla U_{k+1} = 0.$$

To conclude the proof, it suffices to note that some contributions of F_{k+2}^A vanish too. \square

The problem $pb^{(k)}$ calls for the use of a parameter b_k , which seem to be related to a forthcoming problem $PB^{(k+1)}$ through the relationship

$$b_k = \int_{\mathbb{T}^d} N_{k+1}(X) \, dX - D^{-1} \int_{Y < 0} G_{k+1}(X, Y) \, dX \, dY.$$

However we know prove that the definition of b_k is a consistent:

Proposition 7. *Coefficients b_k (see the definition of $pb^{(k)}$ and $PB^{(k+1)}$) satisfying Eq. (7) only depend on the elementary solutions $(u_j, p_j, \sigma_j)_{j < k}$ and $(U_j, P_j, \Sigma_j)_{j \leq k}$.*

Proof. The source contribution G_{k+1} only depends on the already defined elementary solutions $((u_j, p_j, \sigma_j)$, $j < k$ and (U_j, P_j, Σ_j) , $j \leq k$). Only one term in the boundary contribution N_{k+1} does not depend on these elementary solution: $N_{k+1}^B = (\nabla H \cdot \nabla_x) \sigma_{k-1}|_{\gamma_0^-}$. Nevertheless, its X -average is equals to 0. \square

The resulting application of Propositions 6 and 7 leads to the following algorithm which allows us to build the approximation of the solution at any fixed order of precision:

Initialization:

 Compute a_0 (compatibility of problem PB⁽²⁾ at the top)
 Compute b_0 (compatibility of problem PB⁽¹⁾ at the bottom)
 Compute (u_0, p_0, σ_0)
 Compute (U_1, P_1, Σ_1)

Iterative process on k :

FOR $k = 1, \dots, +\infty$, DO

 Compute a_k (compatibility of problem PB^($k+2$) at the top)
 Compute b_k (compatibility of problem PB^($k+1$) at the bottom)
 Compute (u_k, p_k, σ_k)
 Compute $(U_{k+1}, P_{k+1}, \Sigma_{k+1})$

END

7. CONCLUDING REMARKS

7.1. Boundary conditions. The diffusive Oldroyd model is generally associated to Neumann boundary conditions for the elastic stress tensor [30], as suggested by the interpretation of the stress diffusion term as arising from the diffusion of polymeric dumbbells [18]. However some authors also considered Dirichlet boundary conditions [31] or mixed boundary conditions [2]. We emphasize that the method that has been developed in this paper readily adapts to the consideration of Dirichlet boundary conditions: the definition of the elementary problems has to be adapted and, in particular, the behaviour at infinity of the boundary layer elastic tensor corrector is completely determined by an exponential decay towards a constant which can be counter-balanced by using a suitable elementary problem at next order.

7.2. Influence of the curvature of the channel. The analysis of the roughness effects has been led in a particular geometry: a channel. When considering space-varying profiles of the boundary such as nozzles or more general converging-diverging profiles, additional coupling effects have to be taken into account. Although the methodology developed in this paper still applies, source terms have to be added in the elementary problems in order to include the scale effects at the macroscopic scale onto the boundary term which serves as a correction in the boundary layer problems. However, there is no additional difficulty from the mathematical point of view, although it tends to increase the complexity of the description of the elementary problems.

7.3. The non-diffusive model. In many studies the standard Oldroyd model is considered without diffusion of the elastic stress tensor. The link between the standard model and the diffusive model has been investigated from the numerical point of view by the authors [16] by considering the vanishing diffusion process in the diffusive model. In the context of the roughness issue, the adaptation of our analysis is questionable when considering the standard Oldroyd model only. Although the two models are very close (at least formally in the regime $D \rightarrow 0$), the asymptotic expansion proposed in this paper does not apply to the case $D = 0$, even formally. This is due to the degeneracy of the boundary conditions: first, the loss of the boundary conditions in the standard model prevents us from developing the current strategy which is based upon the correction of the boundary terms at higher orders ; second,

ignoring the specific treatment of the boundary conditions that was done in the diffusive model provides inconsistent elementary problems.
